The World Drug Report provides an annual overview of the major developments in drug markets for the various drug categories, ranging from production to trafficking, including development of new routes and modalities, as well as consumption. Chapter 1 of the World Drug Report 2014 provides a global overview of the latest developments with respect to opiates, cocaine, cannabis and amphetamines (including "ecstasy") and the health impact of drug use. Chapter 2 zeroes in on the control of precursor chemicals used in the manufacture of illicit drugs.

World Drug Report
2014
The World Drug Report 2014 is aimed at helping the international community to address the toll that illicit drug production, trafficking and consumption continues to take on all our societies, by providing a global overview and analysis of developments, based on the best available data.

The report is being published at a key moment in the global debate on the world drug problem. A high-level review of the implementation of the Political Declaration and Plan of Action on International Cooperation towards an Integrated and Balanced Strategy to Counter the World Drug Problem was conducted in March 2014 in Vienna by the Commission on Narcotic Drugs, followed by a regular session of the Commission. These meetings provided contributions to a special session of the General Assembly on the world drug problem, which will be held in 2016. The high-level review was more than a stocktaking exercise; it provided a much-needed forum for an open, inclusive dialogue, involving not just Governments but also the scientific community, civil society and young people, on the most effective ways to counter the world drug problem.

Efforts to date to implement the Political Declaration and Plan of Action have resulted in some considerable successes, including sustainable reductions in illicit drug cultivation through alternative development initiatives and welcome improvements in treatment delivery. There have also undeniably been serious setbacks, however, not least the surge in opium cultivation and production in Afghanistan, the violence associated with the illicit drug trade, and the growing instability of regions, including West and East Africa, that are already vulnerable to trafficking and to rising levels of local production and use of illicit drugs.

It is clear from the discussions at the high-level review, and from the findings of the present report, that there are no simple answers to these problems. Nevertheless, the lessons we have learned are valuable and we have attained a shared understanding of a way forward.

First and foremost, we have learned that sustainable success requires a balanced, cooperative, comprehensive and integrated approach, addressing both supply and demand. This was emphasized in the Joint Ministerial Statement resulting from the High Level Review, in which governments reaffirmed the international drug conventions as the health and human rights-centred cornerstone of the drug control system, and pledged to strengthen cooperation.

A balanced approach relies on evidence-based responses, with a firm emphasis on public health, and includes measures focusing on prevention, treatment and social rehabilitation and integration.

There remain serious gaps in service provision, with only one in six problem drug users accessing drug dependence treatment services each year. The new set of data on access to services presented in the World Drug Report this year can support Member States in addressing this crucial area more effectively.

In addition, for the first time the report presents joint estimates by the United Nations Office on Drugs and Crime (UNODC), the World Health Organization, the Joint United Nations Programme on HIV/AIDS (UNAIDS) and the World Bank on the number of people who inject drugs and the number of people who inject drugs and are living with HIV. I welcome these cooperative efforts, which are very much in the spirit of “One United Nations” and can help countries to address the discrimination that continues to hinder access to HIV prevention, treatment and care services, particularly for people who use drugs and for those in prison.

As the chair of the UNAIDS Committee of Cosponsoring Organizations this year, UNODC is committed to ensuring evidence-informed HIV interventions for all key populations. We have seen that countries that have adequately invested in harm reduction services have lowered remarkably HIV transmission among people who inject drugs.

The World Drug Report 2014 also addresses another important area, namely the results achieved and the challenges the international community continues to face in controlling precursors. All drugs, whether plant-based or synthetic, require chemicals for their manufacture or processing. An international control system facilitating the legal trade of such chemicals while avoiding their diversion must be very robust, particularly as we continue to see rises in the manufacture and trafficking of synthetic drugs, which cannot be controlled through traditional supply reduction approaches such as crop eradication.

Changes in the international manufacture and trade of chemicals present challenges. Evidence shows, however, that measures to control precursor chemicals have had a tangible impact in reducing their diversion for illicit manufacturing of drugs, and this must remain a key supply control strategy. The work of the International Narcotics Control Board and its cooperative mechanisms is central in this regard. The international drug conventions entrust the Board with assessing the implementation of measures to control precursors at the international level and supporting countries to strengthen efforts to prevent diversion.

More broadly, we must continue to enhance international cooperation, including with respect to transparent sharing of data and analysis, to help us better understand the drug problem and address the many challenges, including the related issues of violence and insecurity. This is particularly important as we move towards the special session of the General Assembly on the world drug problem in 2016. I hope the World Drug Report 2014 will serve as a tool in these efforts, providing evidence to support the international community in devising more effective policies and finding joint solutions.

Yury Fedotov

Review and comments
Valuable comments and contributions were received from Conor Crean, Natascha Eichinger, Martin Raithelhuber and Justice Tettey (Laboratory and Scientific Section) and from several colleagues from the Division for Operations, the Division for Treaty Affairs and the secretariat of the International Narcotics Control Board.

The Research and Trend Analysis Branch is also grateful for the valuable advice provided by the following experts:
Michael A. Cala
Jesus Maria García Calleja
Jonathan Caulkins
Karl L. Dehne
Peter Reuter
Keith Sabin

The report also benefited from the work and expertise of many other UNODC staff members in Vienna and around the world.

EXPLANATORY NOTES

The boundaries and names shown and the designations used on maps do not imply official endorsement or acceptance by the United Nations. A dotted line represents approximately the line of control in Jammu and Kashmir agreed upon by India and Pakistan. The final status of Jammu and Kashmir has not yet been agreed upon by the parties. Disputed boundaries (China/India) are represented by cross hatch due to the difficulty of showing sufficient detail.

The designations employed and the presentation of the material in this publication do not imply the expression of any opinion whatsoever on the part of the Secretariat of the United Nations concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries.

Countries and areas are referred to by the names that were in official use at the time the relevant data were collected.

Since there is some scientific and legal ambiguity about the distinctions between “drug use”, “drug misuse” and “drug abuse”, the neutral terms “drug use” and “drug consumption” are used in this report.

The data on population used in this report are from: United Nations, Department of Economic and Social Affairs, Population Division, World Population Prospects: The 2012 Revision.

References to dollars ($) are to United States dollars, unless otherwise stated.

When referring to drug use, all mentions of amphetamine-type stimulants exclude “ecstasy”.

References to ‘tons’ are to metric tons, unless otherwise stated.

The World Drug Report provides an annual overview of the major developments in drug markets for the various drug categories, ranging from production to trafficking, including development of new routes and modalities, as well as consumption. Chapter 1 of the World Drug Report 2014 provides a global overview of the latest developments with respect to opiates, cocaine, cannabis and amphetamines (including ‘ecstasy’) and the health impact of drug use. Chapter 2 zeroes in on the control of precursor chemicals used in the manufacture of illicit drugs.

Drug use and its health and social consequences

Drug use continues to exact a significant toll, with valuable human lives and productive years of many persons being lost. An estimated 183,000 (range: 95,000-226,000) drug-related deaths were reported in 2012. That figure corresponds to a mortality rate of 40.0 (range: 20.8-49.3) deaths per million among the population aged 15-64. While that estimate is lower than for 2011, the reduction can be ascribed to the lower number of deaths reported in the year 2012.

That said, each region exhibits its own peculiarities with respect to specific drugs. Polydrug use, which is generally understood as the use of two or more substances at the same time or sequentially, remains a major concern, both from a public health and a drug control perspective.

Although the general public may perceive cannabis to be the least harmful illicit drug, there has been a noticeable increase in the number of persons seeking treatment for cannabis use disorders over the past decade, particularly in the Americas, Oceania and Europe. Nonetheless, opiates remained the most prevalent primary drug of abuse among those seeking treatment in Asia and in Europe, as did cocaine in the Americas.

With regard to injecting drug use, the United Nations Office on Drugs and Crime (UNODC), the Joint United Nations Programme on HIV/AIDS (UNAIDS), the World Bank and the World Health Organization (WHO), drawing on the most recent data available, jointly estimate that the number of people who inject drugs is 12.7 million (range: 8.9 million-22.4 million). That corresponds to a prevalence of 0.27 per cent (range: 0.19-0.48 per cent) of the population aged 15-64. The problem is particularly stark in Eastern and South-Eastern Europe, where the rate of injecting drug use is 4.6 times higher than the global average.

The sharing of used injecting equipment makes people who inject drugs particularly vulnerable to HIV and hepatitis C. It is estimated that an average of 13.1 per cent of the total number of people who inject drugs are living with HIV. UNODC, the World Bank, WHO and UNAIDS jointly arrived at a global estimate of the number of people who inject drugs living with HIV of 1.7 million persons (range: 0.9-4.8 million). That situation is particularly pronounced in two regions of the world: South-West Asia and Eastern/South-Eastern Europe, where it is estimated that the prevalence of HIV among people who inject drugs is 28.8 and 23.0 per cent, respectively. More than half of the people who inject drugs are estimated to be living with hepatitis C.

Addressing HIV among people who inject drugs, through the implementation of an evidence-based comprehensive package of nine interventions, as a component of what is
also known as “harm reduction services”, is a major component of the global response to stop the spread of HIV. Of them, the four most effective interventions for HIV prevention, treatment and care are needle and syringe programmes, opioid substitution therapy (or other evidence-based drug dependence treatment in the case of people who inject non-opioid drugs), HIV testing and counselling, and antiretroviral therapy.

The coverage of the four most effective interventions is greatest in Western and Central Europe, where harm reduction interventions have been scaled up for more than a decade, leading to a decline in the number of newly diagnosed cases of HIV among people who inject drugs and of AIDS-related deaths attributed to unsafe injecting drug use. However, recent outbreaks of HIV among people who inject drugs in parts of Europe demonstrate how the HIV epidemic situation can change very rapidly in areas where services and interventions are scaled down.

It is well documented that a very high percentage of people who inject drugs have a history of imprisonment. Also, both drug use and injecting drug use are highly prevalent among prison populations. The lack of access to and availability of health care, especially drug dependence treatment and HIV prevention, treatment and care services in prisons, is of major concern, since the prison population, at a minimum, should have access to services equivalent to those available to the general public. For instance, in Europe, the proportion of prisoners who had used an illicit substance during incarceration ranged from 4-56 per cent.

In Europe, the financial crisis seems to have had an impact on drug use modalities, with related health and social consequences. While there are no comprehensive data available yet, two phenomena seem to have emerged in parts of Europe that have appeared in parallel to the financial crisis. First, there appears to be a shift in the pattern of drug use which sometimes results in a higher risk of harm; and secondly, there has been a reduction in coverage of harm reduction services, which, according to recently published research, has increased the likelihood of unsafe injecting behaviour, thus influencing the spread of infections such as HIV and hepatitis C.

Drug profiles by category

**Opiates**

Opiates and opioids top the list of problem drugs that cause the most burden of disease and drug-related deaths worldwide. For the third consecutive year, Afghanistan, which has the world’s largest opium poppy cultivation, saw an increase in the area under cultivation (from 154,000 hectares in 2012 to 209,000 hectares in 2013). In addition, Myanmar witnessed expansion in the area of opium poppy cultivation, although less pronounced. In 2013, the estimated global production of heroin rebounded to the levels seen in 2008 and 2011. The global area of illicit opium cultivation in 2013 stood at 296,720 hectares — the largest area since 1998, when estimates became available.

There is evidence that Afghan heroin is increasingly reaching new markets, such as Oceania and South-East Asia, that had been traditionally supplied from South-East Asia. The long-established Balkan route seems to remain a corridor for the transit of Afghan heroin to the lucrative markets in Western and Central Europe, but its importance has declined due to various factors such as more effective law enforcement and a shrinking market in Western and Central Europe, as seen by the decline in opiate use and seizures in the subregion and the reduced level of supply compared with the peak levels of 2007.

The so-called “southern route” is expanding, with heroin being smuggled through the area south of Afghanistan reaching Europe, via the Near and Middle East and Africa, as well as directly from Pakistan.

An emerging phenomenon among opioid-dependent drug users in the United States of America is that synthetic opioids are being replaced with heroin, driven by the increased availability of heroin in parts of the United States, and lesser costs to regular users to maintain their dependency. Further, the reformulation of one of the main prescription pharmaceuticals abused, OxyContin, now makes it more difficult to snort or inject it.

Following a sharp increase in 2011, global seizures of heroin and illicit morphine declined in 2012, while remaining higher than the levels of 2010 and prior years. The fluctuations were mainly driven by seizures in South-West Asia and Western and Central Europe. However, in 2012, there was an increase in heroin seizures in many other regions, mainly Eastern and South-Eastern Europe, South Asia and Oceania. Significantly, heroin seizures, and therefore presumably the flow of heroin, in key countries located along the “northern route” from Afghanistan to the Russian Federation, have gone down. At the same time, there is evidence of a significant number of small seizures of home made desomorphine, which is likely serving as a substitute for heroin.

The emergence of potentially more harmful behaviour, including the abuse of opioids such as fentanyl, has been noted among opioid-dependent persons in Estonia, Finland and the United States. It has been observed that opioid users may alternate between pharmaceutical and/or prescription opioids and heroin, depending on which substance is more available, accessible and cheaper in the market.

**Cocaine**

While cocaine manufacture and trafficking have had a serious impact in the Western hemisphere, there are indications that overall global availability of cocaine has fallen. The estimated net area under coca bush cultivation as of 31 December 2012 was the lowest since the beginning of
available estimates in 1990: 133,700 hectares, a decline of 14 per cent from the estimate for 2011.

Global cocaine seizures increased to 671 tons in 2012, compared with the 634 tons seized in 2011. The main increase in the quantities of cocaine seized were in South America and Western and Central Europe.

Cocaine use is still relatively concentrated in the Americas, Europe and Oceania, and practically all of the world’s cocaine is produced in three countries in South America. While there is no conclusive evidence with respect to the extent of cocaine use in Africa and Asia, expert opinion indicates that there may be pockets of emerging cocaine use in those two regions, related to the rise in trafficking through Africa and increased affluence in both continents.

The most problematic use of cocaine is in the Americas. In North America, cocaine use has been declining since 2006, partly due to a sustained shortage. However, more recently, a slight increase in prevalence has been observed in the United States, as has an increase in maritime seizures.

In South America, cocaine consumption and trafficking have become more prominent, particularly in Brazil due to factors including its geographical location and a large urban population.

In Western and Central Europe, the second largest market after the Americas, indicators of overall supply suggest a possible rebound in the availability of cocaine; retail purity has increased in some countries with sizable consumer markets. On the other hand, they do not show an increase in demand. There has even been a decline in cocaine use in some of the countries that have had higher levels of use.

The market has expanded in Oceania in recent years, but the region has a different pattern of use compared with other consumer markets because it has a large body of users (a high prevalence) who use the substance with low frequency, perhaps due to the high price of cocaine.

Cannabis

Cultivation and production of cannabis herb (“marijuana”) remains widespread, while production of cannabis resin (“hashish”) remains confined to a few countries in North Africa, the Middle East and South-West Asia. In Afghanistan, despite the fact that the area under cannabis cultivation has been decreasing, the potential cannabis resin production in 2012 was higher than in 2011 due to the greater yield per hectare.

Global cannabis use seems to have decreased, essentially reflecting a decrease in cannabis use estimates reported by a number of countries in Western and Central Europe. However, in the United States, the lower perceived risk of cannabis use has led to an increase in its use. At the same time, more people using cannabis are seeking treatment each year.

In Europe, the market has changed over the past decade, with cannabis herb produced locally or regionally now gaining ground over cannabis resin, largely sourced from Morocco, which previously was the dominant cannabis substance in Europe, as evidenced by seizure data.

New regulatory frameworks in the States of Colorado and Washington in the United States and in Uruguay now make the recreational use of cannabis legal under some restrictions. The new laws also include provisions for the supply chain, including both licensed and personal cultivation. It is too early to understand the impact of these changes on recreational and problematic use of cannabis and in the broad range of areas that they may affect, including health, criminal justice, and public revenues and expenditures. It will take years of careful monitoring to understand the broader effects of those novel regulatory frameworks in order to inform future policy decisions.

Based on existing research, it can be argued that with declining risk perception and increased availability, use and youth initiation may increase. Tax revenues from retail cannabis sales are expected to provide public revenue. However, expected revenue will need to be cautiously weighed against the costs of prevention and health care.
Amphetamine-type stimulants

While it is difficult to quantify the global manufacture of amphetamine-type stimulants, the number of dismantled laboratories manufacturing amphetamine-type stimulants, which were mostly manufacturing methamphetamine, continued to rise. Manufacture of methamphetamine in North America expanded once again, with a large increase in the number of methamphetamine laboratories reported dismantled in the United States and Mexico.

Of the total of 144 tons of amphetamine-type stimulants seized globally, half were seized in North America and a quarter in East and South-East Asia. Large quantities of amphetamine seizures continue to be reported in the Middle East, in particular in Jordan, Saudi Arabia and the Syrian Arab Republic.

Central and South-West Asia are emerging as new markets, with low levels of methamphetamine seizures and use being reported by two countries in those subregions. South-West Asia has also emerged as a significant production area for methamphetamine destined for East and South-East Asia. Production in West and Central Africa is also emerging.

Seizures of “ecstasy” increased in 2012, with major quantities of “ecstasy” being seized in East and South-East Asia, followed by Europe (South-Eastern and Western and Central Europe), which together accounted for over 80 per cent of global seizures of “ecstasy”.

The misuse of prescription stimulants or medications for attention-deficit hyperactivity disorder (ADHD) is not uncommon, although only a few countries report any prevalence of misuse among the general and youth population. Although misuse of prescription stimulants in other regions is not negligible, such abuse is reported mainly by countries in North and South America.

New psychoactive substances and web-based marketplaces

While the Internet continues to be used as a means of drug trafficking and illicit trade in precursor chemicals, use of the so-called “dark net” has been growing. The “dark net” constitutes a virtual marketplace, which is inaccessible by web search, and where it is difficult for law enforcement authorities to identify website owners and users, as their identities remain hidden by means of sophisticated concealment methods. That makes the “dark net” a safe haven for buyers and sellers of illicit drugs, who trade principally in a digital currency (Bitcoin).

While the overall proportion of drug transactions that take place in the “dark net” is unclear, the value of transactions, as well as the range of drugs available, appears to be growing. The dismantling of one prominent “dark net” site, the “Silk Road”, uncovered that the site had approximately $1.2 billion worth of total revenue from two to five years of operations. There is evidence of a niche market on the “dark net” for new psychoactive substances as well as for high-quality cannabis, heroin, methylenedioxymethamphetamine (MDMA) and cocaine.

Finally, the proliferation of new psychoactive substances continues to pose a challenge, with the number of new psychoactive substances (348 such substances in December 2013, up from 251 in July 2012) clearly exceeding the number of psychoactive substances controlled at the international level (234 substances).

Drug-related crime

Crime recorded by the authorities in relation to personal use and trafficking of drugs assessed separately has shown an increase over the period 2003-2012, in contrast to the general declining trend in property-related and violent crime. However, the proportion of drug offenders who were drug users with recorded offences for personal use has remained stable, given the increased number of users during that period. Worldwide, the large majority of drug use offences are associated with cannabis.

Crime related to drug trafficking varies depending on the type of drug and the supply patterns involved in different regions.

The majority of persons arrested for or suspected of drug offences are men; the involvement of women in drug offences varies according to drug type, reflecting the drugs of preference among women. The highest percentage of women arrestees or suspects can be observed in relations to crimes involving sedatives and tranquillizers (25 per cent).

Precursor control

Most drugs, whether plant-based or synthetic, require chemicals to transform them into the final product. While chemicals are only one of the components required for the clandestine manufacture of plant-based drugs (heroin and cocaine), they constitute the essential components of illicitly manufactured synthetic drugs.

Given the growing manufacture of synthetic drugs, the control of such chemicals, known as precursors, has emerged as a key supply control strategy because the traditional approaches, such as eradication of illicit crops and alternative development, cannot be applied to synthetic drugs.

There are potential vulnerabilities in the structure of and trends in the production of and trade in chemicals that are used in the illicit manufacture of drugs. The international community has, over the years, strengthened a control system aimed at enabling the legal trade of such chemicals while preventing their diversion into illicit manufacture.

Some successes have been achieved in precursor control, but they have prompted a range of reactions from the traffickers and manufacturers of illicit drugs, which create new challenges for the international drug control system.
Vulnerabilities of the chemical industry to diversion of precursors

The chemical industry has seen strong growth rates and geographical shifts over the past few decades, notably the past two decades, when global production doubled and trade more than tripled. Also during that period, the bulk of production shifted to Asia, where the emerging chemical industry is now characterized by a sizeable cluster of small competing enterprises. In contrast to the past situation, when the chemical industry was dominated by large, vertically integrated conglomerates, these new developments have made the chemical industry potentially more vulnerable to the diversion of precursors.

Moreover, with more and more chemicals being traded across borders, a greater number of transit countries and the emergence of a number of chemical brokers and other intermediaries, the potential avenues for diversion of precursors to the clandestine manufacture of drugs have been increasing.

Response by the international community

Precursor control emerged as one of the key pillars of international drug control in the United Nations Convention against Illicit Traffic in Narcotic Drugs and Psychotropic Substances of 1988. The Convention sets out specific measures for the manufacture and distribution of and international trade in a number of chemicals frequently used in the manufacture of drugs. These are listed under two categories: the more strictly controlled substances in Table I and the relatively less controlled substances in Table II. The 1988 Convention entrusts the International Narcotics Control Board with the implementation of precursor control at the international level.

The system has been further enhanced by means of a number of resolutions adopted by the United Nations Commission on Narcotic Drugs, the Economic and Social Council and the General Assembly, as well as the Political Declaration adopted by the General Assembly at its twenty-fifth special session, in 1998, and the Political Declaration and Plan of Action on International Cooperation towards an Integrated and Balanced Strategy to Counter the World Drug Problem, adopted by the General Assembly in 2009, including their related action plans. As of December 2013, 23 substances were under international control: 15 substances in Table I and 8 substances in Table II of the 1988 Convention. In March 2014, the Commission on Narcotic Drugs decided to schedule alpha-phenylacetoacetonitrile (APAAN) in Table I of the Convention.

Production and trade of precursor chemicals

There is licit use and licit trade of precursors, and control includes the monitoring of the licit trade while preventing diversion. Through the analysis of information provided by countries to UNODC and international trade statistics, it can be concluded that over the period 2010-2012, some 77 countries were engaged in the manufacture of precursor chemicals.

A much larger number of countries were involved in trade in precursors. 122 countries reported exports of precursor chemicals over the period 2010-2012, while 150 countries reported imports. The largest exports of precursors were reported by countries in Asia, followed by Europe and the Americas. If only net exporting countries of precursor chemicals are considered, Asian countries account for 59 per cent of total net exports over the 2010-2012 period. Global exports in precursor chemicals rose at a rate similar to that of chemicals in general.

The licit requirements for and applications of various precursors differ from country to country. The bulk (93 per cent) of the international trade in precursor chemicals, in terms of economic value, is of substances listed in Table II of the 1988 Convention. In 2012, the more strictly controlled substances in Table I accounted for only 7 per cent of international trade in precursor chemicals, or 0.04 per cent of overall international trade in chemicals, and their export growth has been far lower than for Table II substances. The most important Table I substances, in economic terms, are acetic anhydride, used in the manufacture of heroin, followed by potassium permanganate, used in the manufacture of cocaine, and pseudoephedrine, used in the manufacture of methamphetamine.

The illicit trade in precursor chemicals cannot be quantified as easily as can the licit market, but information on seizures can provide some partial information on trends.

Although annual seizures of precursor chemicals fluctuate greatly, the overall trend for Table I precursors seems to show an increase over the last two decades. By contrast, seizures of Table II substances, although fluctuating, have been following a stable trend overall. The regional distribution of seizures of precursors in Table I and Table II shows a concentration in the Americas, followed, depending on the time frame examined, by Europe or, in more recent years, Asia.

Impact of precursor control on drug supply

Measures employed to control precursor chemicals have had a tangible impact on reducing the diversion of chemicals to the illicit manufacture of drugs, as could be observed through various methods of analysis:

a) Increased volume of chemicals saved from diversion. The number of shipments stopped before being diverted increased sharply, and seizures of Table I precursors rose 12-fold from the period 1990-1992 to the period 2010-2012, the former period being the initial years of international precursor control. This may point to the effectiveness of precursor control, although it is not conclusive proof;

b) High interception rates. Measuring seizures compared with the overall amount estimated to have been di-
Verted into illicit manufacture, show that about 15 per cent of diverted potassium permanganate (in the range of 10-28 per cent) and 15 per cent of diverted acetic anhydride (in the range of 7-22 per cent) have been intercepted over the period 2007-2012. Estimated diversions are equivalent to just 2 per cent of international trade in potassium permanganate and 0.2 per cent of international trade in acetic anhydride;

c) Higher volumes of precursor seizures compared with the volume of seizures of the substances those precursors are used to manufacture. Seizures of precursors of “ecstasy”, expressed in terms of the amount of “ecstasy” they could be used to manufacture (end-product equivalent), were almost a fifth larger than “ecstasy” seizures over the period 2007-2012. Seizures of amphetamine and methamphetamine precursors calculated in terms of their end-product equivalents were more than twice as high as amphetamine and methamphetamine seizures over the same period;

d) Reduced availability of drugs due to precursor control. Three examples can be cited in which precursor control appears to have reduced the supply of precursors and led to a consequent reduction in the availability of the drug. The first is the shrinking of the market for lysergic acid diethylamide (LSD), which could be at least partly attributed to improved control of LSD precursors. The shrinking of that market is reflected in the 75 per cent decline in use of LSD among high school students in the United States over the period 1996-2013, which is highly correlated to the decreased availability of the substance. The second example is the decline in “ecstasy” use in many countries, associated with a lower purity of the substance, connected with the limited availability of that drug’s main precursor in the period 2007-2010. Thirdly, the improved control of precursors of methaqualone seems to have led to a decline in its availability and thus also its use over the past two decades;

e) Prices in the illicit market. While the price of acetic anhydride in the licit market fluctuated between $1 and $1.50 per litre in recent years, the price of illicit acetic anhydride in Afghanistan rose over the years, at times reaching peaks of some $430 per litre (2011), up from $8 in 2002. The price rises can be linked to improvements in precursor control. They also had an impact on the cost of heroin production. The proportion of acetic anhydride in total production costs of heroin in Afghanistan rose from 2 per cent in 2002 to 26 per cent in 2010 before falling to some 20 per cent in 2013.

New strategies by operators of drug laboratories

Improved precursor controls at the global level have prompted clandestine operators of illegal laboratories to develop a number of counter-strategies. Those strategies include:

- the use of more sophisticated ways to obtain precursor chemicals
- the use of transit countries with weak control systems
- the emergence of organized criminal groups specialized in the supply of precursor chemicals
- the creation of front companies to conceal illegal imports
- the domestic diversion and subsequent smuggling of precursor chemicals to final destinations in order to bypass the international control system
- the use of the Internet
- the misuse of pharmaceutical preparations (notably preparations containing ephedrine or pseudoephedrine) and,
- the emergence of non-scheduled precursor chemicals, including various pre-precursors that can be easily converted into the required precursors.

Thus, new pre-precursors for the manufacture of amphetamine-type stimulants have emerged in recent years, including APAAN, various esters of phenylacetic acid, 3,4-methylenedioxymethyl-2-propanone, methyl glycinate and methamphetamine. Some of those substances, which are controlled only in a limited number of countries, have become major substitutes for the precursor chemicals used in the past and are now seized in greater quantities than are the internationally controlled precursors of amphetamine-type stimulants.

Another counter-strategy is the manufacture of new psychoactive substances that can be manufactured with chemicals not under international control.

All of these strategies used by clandestine manufacturers create a new set of challenges for the international precursor control system. At the same time, they reflect the fact that precursor control does have an impact. There are already some instruments available at the international level to deal with the emerging problems — use of the “know-your customer” principle, the limited international special surveillance list, the Pre-Export Notifications (PEN) Online and the Precursors Incident Communication System (PICS) — but they are yet to be implemented in a number of countries. Their universal and effective implementation would be a step forward in meeting these challenges.
A. EXTENT OF DRUG USE: GLOBAL OVERVIEW

Globally, it is estimated that in 2012, some 243 million people (range: 162 million-324 million) corresponding to some 5.2 per cent (range: 3.5-7.0 per cent) of the world population aged 15-64 had used an illicit drug — mainly a substance belonging to the cannabis, opioid, cocaine or amphetamine-type stimulant (ATS) group — at least once in the previous year. Although the extent of illicit drug use among men and women varies from country to country and in terms of the substances used, generally, men are two to three times more likely than women to have used an illicit substance. While there are varying regional trends in the extent of illicit drug use, overall global prevalence of drug use is considered to be stable. Similarly, the extent of problem drug use, by regular drug users and those with drug use disorders or dependence, also remains stable, at about 27 million people (range: 16 million-39 million).

With respect to the different groups of substances, there has been an increase in opioid and cannabis use since 2009, whereas the use of opiates, cocaine and ATS (excluding “ecstasy”) has either remained stable or followed a decreasing trend. However, not all countries conduct national surveys on drug use, and most countries that do so conduct them only periodically, once every three to five years.

Therefore, rather than looking at the year-to-year change, it is more meaningful to take a longer-term perspective. Also, year-on-year changes in a country’s prevalence rate have only a slight impact on a region’s overall prevalence unless they occur in a country with a large population. For 2012 data, updated prevalence estimates are available for 33 countries, mostly countries of Western and Central Europe and North America, representing nearly 12 per...
1. RECENT STATISTICS AND TREND ANALYSIS OF THE ILLICIT DRUG MARKET

Recent statistics and trends in the illicit drug market are significant to understanding the global drug epidemic. The United Nations Office on Drugs and Crime (UNODC) provides annual reports on drug use, which include estimates for the prevalence of use and trends. The estimates reflect the use of various substances across different regions, and they are based on surveys and other data sources. The data presented here includes information on the number of users, their prevalence rates, and the global annual estimates of overall drug use and of different substances. The estimates do not always capture the full extent of drug use, especially in regions where data collection is limited. Therefore, the trends and global annual estimates of overall drug use and of different substances reflect only the changes in or revision of the estimates for those countries and regions. The data also reflect the use of both legal and illegal substances, and the prevalence rates can vary significantly by region.

Polydrug use
Polydrug use is the use of two or more substances at the same time or sequentially. It is a common occurrence among both recreational and regular drug users in all regions. There are three distinct patterns of polydrug use:

1. **Cumulative or Complementary Effect**: Different substances are used together to have a cumulative or complementary effect. This pattern is commonly seen among cannabis and cocaine users, who may use the drug in combination with alcohol; other combinations are the use of heroin in combination with benzodiazepines, alcohol or other opioids (methadone, oxycodone, etc.) and the use of cocaine in combination with other stimulants.

2. **Offsetting Effect**: A drug is used to offset the adverse effects of another drug, e.g., cocaine and heroin use (“speedball”), or cocaine use with other opioids, although in the latter case, there is also a complementary effect.

3. **Substitution**: A drug is gradually replacing or being substituted by another drug due to changes in price or availability or because the drug is in fashion. Common examples are heroin being substituted by oxycodone, desomorphine or other opioids, as observed in various regions, or “ecstasy” being substituted by mephedrone or some other new psychoactive substance.

A third pattern is observed when a drug is gradually replacing or being substituted by another drug due to changes in price or availability or because the drug is in fashion. Common examples are heroin being substituted by oxycodone, desomorphine or other opioids, as observed in various regions, or “ecstasy” being substituted by mephedrone or some other new psychoactive substance.

Various studies have documented the extent of polydrug use. In a study conducted in 14 European countries in 2006, 60 per cent of cocaine users were polydrug users, of which 42 per cent used alcohol, 28 per cent used cannabis and 16 per cent used heroin. In another study, in the South-Eastern United States, 48.7 per cent of treatment admissions were for polydrug use, with alcohol, cocaine and cannabis being the most common substances. The main risks and consequences of polydrug use, for both recreational and high-risk drug users, continue to be the severe health consequences due to the increased toxicity, overdose and death. From a policy perspective, it is important to understand the patterns of polydrug use because such use invalidates the established profile and characterization of the user of a specific, single drug.

Source: Estimates based on the UNODC annual report questionnaire.

Drug use and gender
Nearly all drug use surveys indicate that men are more likely than women to use drugs such as opiates and cannabis. However, the gender gap shrinks when data on the misuse of pharmaceuticals are considered. In five recently surveyed countries (Australia, United States of America, Spain, Urban Afghanistan, and Pakistan), the illicit use of drugs is more common among men than women, but the non-medical use of pharmaceutical drugs is nearly equivalent, if not higher among women (see figure 3). Taking together the combined estimates of those five surveys, the illicit use of pharmaceuticals is notably different for the two sexes, as nearly half the women with past-year drug use had used pharmaceuticals, compared with only one third of men.

4 Ibid.
B. HEALTH AND SOCIAL IMPACT

Problematic drug use as reflected in the demand for treatment

The need for treatment for drug use disorders and dependence reflects a problematic level of consumption. Therefore, analysing drug types that contribute to the demand for treatment can provide information on the drugs that have the highest negative impact on health in each region. Treatment for cannabis use is very evident in Africa, throughout the Americas and in Oceania. Although the general public may perceive cannabis to be the least harmful illicit drug, between 2003 and 2012 the proportion of total treatment admissions for cannabis increased in Western and Central Europe (from 19 per cent to 25 per cent), Eastern and South-Eastern Europe (from 8 per cent to 15 per cent), Latin America and the Caribbean (from 24 per cent to 40 per cent) and Oceania (from 30 per cent to 46 per cent). Opioids dominate the demand for treatment in Eastern and South-Eastern Europe and Asia. Cocaine is a major contributor to the demand for treatment in the Americas, in particular in Latin America and the Caribbean. ATS use is responsible for sizeable proportions of treatment demand in Asia and Oceania.

Globally, it is estimated that approximately one in six problem drug users accesses treatment each year. However, there are large regional disparities, with approximately 1 in 18 problem drug users receiving treatment in Africa (primarily for cannabis use), compared with one in five problem drug users receiving treatment in Western and Central Europe, one in four in Oceania, and one in three in North America.

Drug-related deaths

Drug-related death is the most extreme form of harm that can result from drug use. The United Nations Office on Drugs and Crime (UNODC) estimates that there were 183,000 (range: 95,000-226,000) drug-related deaths in 2012, corresponding to a mortality rate of 40.0 (range: 20.8-49.3) deaths per million persons aged 15-64.

The current estimate of the total number of drug-related deaths is a downward revision from the value published in the World Drug Report 2013. However, this should not be interpreted as a decline in the global number of drug-related deaths. That revision was predominantly the result of the updated estimates from only a few countries (Iran (Islamic Republic of), Kazakhstan and Uzbekistan), which mostly affected the regional total for Asia and, consequently, the global number of drug-related deaths.

Drug overdose is the primary contributor to the global number of drug-related deaths, and opioids (heroin and the non-medical use of prescription opioids) are the main drug type implicated in those deaths. Risk factors for overdose include the availability and purity of opioids; reduced tolerance due to a recent period of abstinence such as due to treatment, incarceration or self-imposed abstinence; lack of treatment for opioid dependence; and polydrug use, especially involving benzodiazepines and the use of alcohol.

Deaths from opioid overdose are preventable not only by reducing opioid dependency or restricting supply but also by reversing the effects of opioids after an overdose has occurred. Naloxone, a pure opioid antagonist, is a medication recommended by the World Health Organization in the high-risk consumption of drugs, for example, people who inject drugs, people who use drugs on a daily basis and/or people diagnosed with drug use disorders or as drug-dependent based on clinical criteria contained in the International Classification of Diseases (10th revision) of the World Health Organization and the Diagnostic and Statistical Manual of Mental Disorders (4th ed.) of the American Psychiatric Association, or any similar criteria or definition that may be used.

The definition of drug-related deaths varies among Member States but includes all or some of the following: fatal drug overdoses, deaths due to HIV acquired through injecting drug use, suicide, and unintentional deaths and trauma, due to drug use.

Because of the very limited reporting of data from countries in Africa, an alternative source is used: Louisa Degenhardt and others, “Illicit drug use”, in Comparative Quantification of Health Risks: Global and Regional Burden of Disease Attributable to Selected Major Risk Factors, vol. 1, M. Ezzati and others, eds. (Geneva, World Health Organization, 2004).

(WHO) that can be administered to immediately reverse the effects of an opioid overdose. It is highly effective and safe and has no significant side effects and no potential for misuse.6

A number of countries have implemented community-based programmes that make naloxone more readily available to appropriately trained opioid users, their peers and family members. In the United States, for example, there were 188 local opioid overdose prevention programmes distributing naloxone in 2010, and between 1996 and 2010, those programmes reported 10,171 opioid overdose reversals through use of naloxone.7

### Preventing non-fatal overdose cases

A major health consequence of high-risk drug use — especially among regular opioid users and people who inject drugs — that remains largely underreported is the occurrence of non-fatal overdose cases.8 Various studies conducted among opioid users and people who inject drugs have reported that the large majority of opioid users had survived an overdose episode in their lifetime (ranging between 30 and 83 per cent, as reported in different opioid overdose prevention programs providing naloxone: United States, 2010”, Morbidity and Mortality Weekly Report, vol. 61, No. 6 (17 February 2012), pp. 101-105.

---

6 Ibid.
7 Centers for Disease Control and Prevention, “Community-based...
Unsafe injecting drug use can have very serious health implications due to the high risks of the transmission of blood-borne infections such as HIV, as well as hepatitis B and hepatitis C, contracted by sharing of contaminated injecting equipment. The Joint United Nations Programme on HIV/AIDS (UNAIDS) reports that the number of new cases of HIV among people who inject drugs (PWID) remains high, constituting up to 40 per cent of new infections in some countries and resulting in a major public health challenge. A recent study on the global burden of disease from drug dependence estimated that in 2010, 1,980,000 years of life were lost in conjunction with unsafe injecting drug use, through premature death as a consequence of HIV infection, and a further 494,000 years of life were lost worldwide due to hepatitis C infection.

Knowledge regarding the behaviour and health of people who use drugs, in particular among people who inject drugs, has expanded over the past decade. There has been a considerable effort over the past 10 years to conduct biological and behavioural surveillance studies specifically designed to measure hard-to-reach and hidden key populations (such as people who inject drugs) in order to estimate the size of those populations and the prevalence of infectious diseases, particularly HIV and hepatitis C, among them.

While the number of integrated biological and behavioural surveys carried out to date is not precisely known, it has been estimated that over the past 10 years (from 2003 to 2013) between 125 and 200 behavioural surveillance surveys and integrated biological and behavioural surveys (which include serological tests for HIV and, in some cases, for hepatitis C and syphilis) have been carried out in over 50 countries.

Current estimates are based on the information available on the prevalence of injecting drug use in 89 countries (compared with 83 countries in the World Drug Report 2013), representing 83 per cent of the global population aged 15-64, and the prevalence of HIV among people who inject drugs in 111 countries (compared with 106 countries in the World Drug Report 2013), representing 92 per cent of the estimated global number of people who inject drugs. This represents an improvement in data coverage compared with what was available previously at the time of the published estimates of the former Reference Group to the United Nations on HIV and Injecting Drug Use in 2008, for which the estimate of injecting drug use prevalence was based on data from 61 countries. The estimated prevalence of HIV among people who inject drugs was based on data from 84 countries.

In calculating the 2012 estimates, UNODC, UNAIDS, WHO and the World Bank joined forces and reached out to a broad group of experts from academia, regional, international and civil society organizations to ensure that the scientific approach to the methodology was used and to access the greatest number of data sets available worldwide on the subject. A combination of methodological differences and factors related to data quality makes it a challenging task to reliably assess global and regional change and trends in the epidemic of injecting drug use and HIV among people who inject drugs.

People who inject drugs

The joint UNODC/WHO/UNAIDS/World Bank global estimate for 2012 of the number of people who had recently injected drugs was 12.7 million (range: 8.9 million-22.4 million).
1. RECENT STATISTICS AND TREND ANALYSIS OF THE ILLICIT DRUG MARKET

6 million), corresponding to a prevalence of 0.27 per cent (range: 0.19-0.48 per cent) of the population aged 15-64. There are, however, large regional variations in terms of data coverage and quality.

The current estimate represents a slight downward revision in the number of people who inject drugs worldwide but rather as a revision of the estimate, following the first joint UNODC/WHO/UNAIDS/World Bank data and methodology review and independent expert consultations conducted at the end of 2013. This led to an updating of national estimates on people who inject drugs for 23 countries, including highly populated countries such as China and Indonesia.

By far the highest prevalence of injecting drug use, with a rate 4.6 times the global average, is found in Eastern/South-Eastern Europe, where 1.26 per cent of the population aged 15-64 are estimated to have recently injected drugs. Within that subregion, notably high rates of injecting drug use are observed for the Russian Federation (2.29 per cent), the Republic of Moldova (1.23 per cent), Belarus (1.11 per cent) and Ukraine (0.88-1.22 per cent).

In terms of the actual numbers of people who inject drugs, three countries (Russian Federation, China and the United States) combined account for 46 per cent of the global total.

HIV among people who inject drugs

UNAIDS reports that for the 49 countries for which data are available, the prevalence of HIV among people who inject drugs is at least 22 times higher than among the general population and, in 11 countries, is at least 50 times higher.16

The joint UNODC/WHO/UNAIDS/World Bank global estimate for 2012 of the number of people who inject drugs living with HIV is 1.7 million (range: 0.9 million-4.8 million), corresponding to an average prevalence of HIV among people who inject drugs of 13.1 per cent.

There are great challenges in collecting data on people who inject drugs. They are often hard to reach and difficult to sample. Surveys among people who inject drugs might capture only people currently injecting drugs, and the global estimate of people who inject drugs living with HIV may not fully represent the number of people who have a lifetime history of injecting drug use and are living with HIV but who are not currently injecting drugs.

The current estimate of the prevalence of HIV among people who inject drugs has been revised upwards from the estimate in the World Drug Report 2013. However, since the estimated total number of people who inject drugs has been revised downward, the estimated global number of people who inject drugs living with HIV

---

remains essentially the same. Importantly, the new estimate reflects the results of the first joint UNODC/WHO/UNAIDS/World Bank data and methodology review and independent expert consultations conducted at the end of 2013, which led to updated national estimates for 36 countries, including the three countries with large populations (China, the Russian Federation and the United States).

Two regions stand out as having a very high prevalence of HIV among people who inject drugs. In South-West Asia, it is estimated that 28.8 per cent of people who inject drugs are living with HIV, predominantly reflecting the high prevalence of HIV among people who inject drugs in Pakistan. In Eastern/South-Eastern Europe, an estimated 23.0 per cent of people who inject drugs are thought to be living with HIV, primarily reflecting the high prevalence observed in both the Russian Federation (range: 18.4-30.7 per cent) and Ukraine (21.5 per cent).

In terms of the actual number of people who inject drugs living with HIV, four countries combined (China, Pakistan, the Russian Federation and the United States) account for 62 per cent of the global total.

An examination of the numbers of new cases of HIV diagnosed each year among people who inject drugs provides insight into changes in the epidemic over time and progress towards achieving the target set in the Political Declaration on HIV and AIDS adopted by the General Assembly in 2011 of reducing HIV transmission among people who inject drugs by 50 per cent by 2015. Although the changes in the numbers of newly diagnosed cases may reflect improved surveillance, they also reflect changes in the transmission of HIV within that most-at-risk group.

In several European countries with a high occurrence of newly diagnosed cases (incidence) of HIV among people who inject drugs, there was a noticeable peak in the number of new cases between 1999 and 2003, indicating that the epidemic in the region was greatest in those years and subsequently declined. That development is visible also in the sharp decline in the number of deaths from AIDS attributed to unsafe injecting drug use that occurred in later years in the western part of the WHO European region, with the number of deaths declining from 1,358 in 2006 to 179 in 2012. During that time period, the contribution of unsafe injecting drug use to total AIDS-related deaths in that region declined from 43 per cent to 25 per cent. The decline in newly diagnosed HIV cases and AIDS-related deaths among people who inject drugs are consistent with the scaling-up of the provision of harm reduction services, a decline in the prevalence of injecting

17 Political Declaration on HIV and AIDS: Intensifying Our Efforts to Eliminate HIV and AIDS (General Assembly resolution 65/277, annex).
18 Countries of Western and Central Europe and Eastern and South-Eastern Europe.
19 For the list of countries of the European region as defined by WHO for the purposes of its work, see www.euro.who.int/en/countries.
20 European Centre for Disease Prevention and Control/WHO Regional Office for Europe. HIV/AIDS surveillance in Europe 2012.
and a change in the behaviour of people who inject drugs, with less frequent injecting and safer injecting practices being observed in many Western European countries.\textsuperscript{21}

There are some exceptions to the general downward trend in the number of new HIV cases among people who inject drugs in Europe, which demonstrate how the situation with regard to the HIV epidemic can change very rapidly. Greece (Athens) and Romania recently experienced significant increases in HIV cases among people who inject drugs. Those outbreaks were related to the increased frequency of injecting associated with a changing pattern of injecting, from heroin to cocaine in Greece and to amphetamines in Romania, and an increase in the sharing of needles and syringes.\textsuperscript{22,23} The European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) notes a temporal association between those outbreaks and the low levels of harm reduction services in Greece (compared with international standards) and Romania.\textsuperscript{24}

Eastern/South-Eastern Europe has very high prevalence rates and numbers of people who inject drugs and people who inject drugs and are also living with HIV, predominantly reflecting the situation in the Russian Federation and Ukraine. In those two countries, the number of people who inject drugs who are newly diagnosed with HIV each year continues to be higher than in other countries of the region. According to the Russian Federal Research and Methodological Centre for Prevention and Control of AIDS, the proportion of newly diagnosed cases of HIV attributed to injecting drug use was 58.7 per cent in 2009 and 57.0 per cent in 2013. In Ukraine, the number of newly diagnosed cases of HIV among people who inject drugs is levelling off at about 6,000–7,000 new cases annually. In Central Asia, a region with a high prevalence of injecting drug use, several countries with a high occurrence of newly diagnosed cases (incidence) of HIV among people who inject drugs have seen the incidence continue to rise over the past decade.\textsuperscript{25} Very high levels of risky injecting behaviour are reported in the region and, although some progress has been made in the scaling-up of HIV prevention, treatment and care services for people who inject drugs, many obstacles still remain.\textsuperscript{26}

22 EMCDDA, “HIV outbreak among injecting drug users in Greece” (Lisbon, November 2012).

24 EMCDDA and European Centre for Disease Prevention and Control, “Joint EMCDDA and ECDC rapid risk assessment. HIV in injecting drug users in the EU/EEA, following a reported increase of cases in Greece and Romania” (Lisbon, January 2012).

25 The initial peak in reported HIV incidence in Central Asia in the early 2000s is also in part related to the increase or initiation of HIV testing among people who inject drugs.

26 Claire Thorne and others, “Central Asia: hotspot in the worldwide HIV epidemic”, \textit{Lancet Infectious Diseases}, vol. 10, No. 7 (July 2010).
South-West Asia has the highest prevalence of HIV among people who inject drugs, with Pakistan contributing the most to that prevalence rate, as that country has a large number of people who inject drugs and a very high prevalence of HIV among people who inject drugs (37 per cent). In Pakistan, a recent cohort study conducted in three drop-in centres in Karachi followed 636 HIV-negative people who injected drugs over a period of two years (between 2009 and 2011). Even though all of those participating in the study were attending basic risk reduction programmes, the HIV incidence rate among them was 12.4 per 100 person-years. At the end of the 24-month study period, 24.9 per cent of the participants were HIV-positive. The authors reported that underfunding compromised the quality and quantity of outreach services and the full implementation of harm reduction programmes. The greatest risk factor for HIV infection was found to be the sharing of syringes, for which the risk of infection was 2.3 times higher than for those who did not share injecting equipment. The authors concluded that the absence of opioid substitution therapy and inadequate needle and syringe programme coverage undermined the success of the HIV harm reduction programmes studied. Other countries of South-West Asia might have similarly high levels of HIV incidence among people who inject drugs, but there is a lack of available data.

### Hepatitis among people who inject drugs

Hepatitis B and C can lead to liver disease such as cirrhosis, liver cancer and death. Hepatitis C is highly prevalent among people who inject drugs and is transmitted through the sharing of contaminated injecting equipment even more easily than is HIV. The first year of injecting is the time of greatest risk for hepatitis C infection from sharing needles and syringes. The joint UNODC/WHO/UNAIDS/World Bank global estimate for 2012 of the percentage of people who inject drugs who are living with hepatitis C is 52.0 per cent, corresponding to 6.6 million people aged 15-64. For 2012, the global estimate of the percentage of people who inject drugs living with hepatitis B is 6.7 per cent, corresponding to 850,000 people aged 15-64.

### Coverage of services for the prevention and treatment of HIV among people who inject drugs

Addressing HIV among people who inject drugs is a major component of the global response to the spread of HIV. A comprehensive package of nine evidence-based interventions, as a component of what are also known as “harm reduction” services, for the prevention, treatment and care of HIV among people who inject drugs, as outlined in the

Note: The table provides the classification and level of service provision for HIV testing and counselling, needle and syringe programmes, opioid substitution therapy and antiretroviral therapy among people who inject drugs and those among them living with HIV, according to the Technical Guide; the percentage of countries reporting low, medium or high coverage for those services, and the global average level of service provision.

a Based predominantly on behavioural survey data.

### Map 1. Service coverage for people who inject drugs and those among them living with HIV, classified according to the Technical Guide

Source: UNODC annual report questionnaire, UNAIDS and the former Reference Group to the United Nations on HIV and Injecting Drug Use.

Note: In reporting on the level of service coverage via the annual report questionnaire, Member States have the option of categorizing the level of service coverage as “not applicable”. That response has been interpreted as meaning that there is no service coverage. For some countries the level of service coverage for needle and syringe programmes is not known, but the service is known to exist in that country. However, the scale of provision of needle and syringe programmes in those cases can vary substantially.

The boundaries shown on this map do not imply official endorsement or acceptance by the United Nations. Dashed lines represent undetermined boundaries. Dotted line represents approximately the Line of Control in Jammu and Kashmir agreed upon by India and Pakistan. The final status of Jammu and Kashmir has not yet been agreed upon by the parties. The final boundary between the Republic of Sudan and the Republic of South Sudan has not yet been determined.

---

**WHO, UNODC, UNAIDS Technical Guide**

(30) (referred to hereafter as the *Technical Guide*) has been widely endorsed by high-level political bodies including the General Assembly, the Economic and Social Council, the Commission on Narcotic Drugs and the Programme Coordinating Board of UNAIDS. In addition, donor agencies, including the Global Fund to Fight AIDS, Tuberculosis and Malaria (GFATM) and the United States President’s Emergency Plan for AIDS Relief (PEPFAR) have committed to using that framework.

In order of priority, the four most important interventions are needle and syringe programmes, opioid substitution therapy, HIV testing and counselling, and antiretroviral therapy.

National estimates of the level of service coverage in the community (the extent to which people who inject drugs actually receive the intervention) and the distribution of needles and syringes are presented using a classification of “low”, “medium” or “high” as defined according to the targets set in the *Technical Guide*.

In most countries, the extent of services provided to people who inject drugs falls below the lower-level targets presented in the *Technical Guide*. However, global estimates mask important regional variations.

The coverage of services is highest in Western and Central Europe, with 50-60 per cent of reporting countries indicating that a high proportion of people who inject drugs are accessing needle and syringe programmes, opioid substitution therapy, HIV testing and counselling and antiretroviral therapy services. In Eastern/South-Eastern Europe, despite the increase in service availability in some countries, access to needle and syringe programmes in particular remains low. In North America, none of the countries report a high level of access of people who inject drugs to any of the services, with needle and syringe programmes consistently reaching only a low proportion of people who inject drugs. In Latin America (no countries from the...
Caribbean reported information), the two overall most important interventions (needle and syringe programmes and opioid substitution therapy) are generally reaching only low numbers of people who inject drugs. It should be noted that in Latin American countries, the prevalence of use of opiates is very low and therefore, in reporting by countries, opioid substitution therapy would not be indicated as relevant. Also six of the seven Latin American countries reporting through the annual report questionnaire indicated that needle and syringe programmes were “not applicable”, reflecting that the practice of injecting drugs is at a low level. In Central Asia and Transcaucasia, a region with a high prevalence of injecting drug use, only two countries indicate a high level of HIV testing and counselling, and access to needle and syringe programmes, and overall low levels of access to opioid substitution therapy. In East and South-East Asia, a region with a large number of people who inject drugs and, among them, a significant number of people living with HIV, 50 per cent of the countries reporting indicate a high level of HIV testing and counselling among people who inject drugs. However, needle and syringe programmes are not reaching many people who inject drugs in many countries in the region. South-West Asia has the highest prevalence of HIV among people who inject drugs, but no country in the region reported a high level of coverage for any of the services. In the 16 countries32 that have the highest prevalence of people who inject drugs and the highest prevalence of HIV among people who inject drugs — which account for 45 per cent of the global number of people who inject drugs and 66 per cent of the global number of people who inject drugs living with HIV — a generally low level of service provision can be noted, particularly with regard to needle and syringe programmes and opioid substitution therapy.

Drug use among prisoners and implications for health

It is estimated that worldwide, on any single day, there are more than 10.2 million people held in prisons (including pretrial detention), with the numbers growing in every continent.33 However, prison population rates differ considerably from region to region and between different parts of the same continent.34 Many of those held are incarcerated for offences related to the use, possession or supply of drugs.

Drug use and injecting drug use are both highly prevalent among prison populations, often more so than among the general population. EMCDDA reports that the proportion of prisoners who had used an illicit substance during incarceration in individual countries in Europe (mostly Western and Central Europe) ranged from 4 to 56 per

32 Belarus, Canada, Georgia, Indonesia, Kazakhstan, Latvia, Malaysia, Myanmar, Pakistan, Republic of Moldova, Russian Federation, Spain, Tajikistan, Thailand, Ukraine and United States. Other countries which have higher prevalence rates may not be included in this list due to lack of reporting of service provision data.

34 The World Prison Population List (10th ed.) indicates that the median prison population rate per 100,000 for West African countries is 46; Southern African countries: 20%; North American countries: United States: 716; Canada: 118; South American countries: 202; Caribbean countries: 376; South/Central Asian countries (mainly the Indian subcontinent): 62; East Asian countries: 160; Western European countries: 98; countries spanning Europe and Asia (e.g., Russian Federation and Turkey): 225; and Oceania: 151.
Global Burden of Disease Study 2010: Estimating the burden of disease from drug dependence

Illicit drug use can have a profoundly negative effect on a person’s health. It can lead to premature death, such as in the case of overdose, but can also severely curtail the quality of life through disability (any short-term or long-term health loss), such as from liver disease, or infection with HIV and hepatitis B and C as a result of sharing contaminated needles and syringes.1

These effects can be quantified in an indicator called “disability-adjusted life year” (DALY), which encompasses both the years of potential life lost due to premature death (YLL) and the years of life lived with disability (YLD). A recent study published by Degenhardt and others (2013)2 produced global estimates of disability-adjusted life years for illicit drug dependence3, and drug use as a risk factor for other health outcomes (schizophrenia from cannabis use, hepatitis and HIV from injecting drug use, and drug dependence as a risk factor for suicide). The findings of that study reveal that in 2010, drug dependence on illicit drugs was responsible for 3.6 million years of life lost through premature death and 16.4 million years of life lived with disability globally. Combined, this is equal to 20 million years of disability-adjusted life years (representing 0.8 per cent of global all-cause disability-adjusted life years), an increase from 13.1 million years estimated for 1990. Opioid dependence contributed most to the burden of disease, being responsible for 55 per cent of years of life lost due to premature death and 44 per cent of years of life lost through disability. The increase in the global burden of disease from cannabis, amphetamine and cocaine dependence between 1990 and 2010 is essentially attributable to population growth, but this is not the case for opioid dependence. The burden of disease from opioid dependence increased by 74 per cent between 1990 and 2010, with 42 per cent of that increase attributable to an increase in the prevalence of opioid dependence. According to UNODC data, the prevalence of opioid use has been increasing globally over the past five years as a consequence of the increased misuse of prescription opioids, whereas the prevalence of opiate (heroin and opium) use has been stable at the global level and declining in some regions such as Europe. A total of 43,000 deaths were attributed to opioid dependence in 2010, which suggests that life expectancy was typically cut short by 46 years in each of those cases of death. The global burden of disease attributed to cannabis dependency is higher than that for cocaine. Although cocaine use is associated with greater harm, the far higher number of cannabis-dependent users results in the greater global burden of disease overall. Broadly speaking, males contribute two thirds of the number of years of life lost and years lived with disability for all drug types. Disability-adjusted life years rose sharply between the ages of 15-24, reaching a peak in the relatively young 20-30 age group, consistently across all drug types. Illicit drug use was estimated to be the cause of 0.8 per cent of disability-adjusted life years worldwide in 2010 (ranking as the 19th leading risk factor). In comparison, tobacco smoking was the cause of an estimated 6.3 per cent of global disability-adjusted life years, and alcohol the cause of an estimated 3.9 per cent. However, for drug use, disability-adjusted life years reach a peak among users aged 20-30 years, and among that age group it contributes a higher proportion to the burden of disease.

The burden of disease from acquiring HIV through injecting drug use was estimated to be 2.1 million years in 2010, of which 2.0 million were from years of life lost through premature death. The burden of disease from hepatitis C acquired through injecting drug use is also high and was estimated to be responsible for 494,000 years of life lost in 2010 through premature death.

1 WHO, Neuroscience of psychoactive substance use and dependence (Geneva, 2004).
2 L. Degenhardt and others, "Global burden of disease attributable to illicit drug use and dependence: findings from the Global Burden of Disease Study 2010".
3 Defined as the presence of three or more indicators of dependence for at least a month within the previous year. These indicators consist of a strong desire to take the substance, impaired control over use, a withdrawal syndrome on ceasing or reducing use, tolerance to the effects of the drug, the need for larger doses to achieve the desired psychological effect, a disproportionate amount of time spent by the user obtaining, using and recovering from drug use, and persistence of drug taking despite the problems that occur.

Several studies document that a very high percentage (56-90 per cent) of people who inject drugs report a history of imprisonment since starting injecting.36 An overview of HIV in prisons in all regions identified rates of infection many times higher than among the general popu-
A study that compiled information on HIV prevalence in prisons for 75 low-income and middle-income countries found rates greater than 10 per cent in 20 of those countries.38 The situation is of particular concern in women’s prisons. Although there are fewer women in prison, both drug use and HIV infection are more prevalent among women in prison than among imprisoned men.39

Although the availability of data is limited, there is a high level of illicit substance use in prisons, in particular the regular use of opioids.40 Injecting drugs is also a common practice. This is of concern because the prison environment is one in which there are limited prevention and treatment options for dealing with drug dependence and its associated health consequences.

The lack of access to and availability of health care, especially drug dependence treatment and HIV prevention and care services, in prisons is of major concern, since the prison population, at a minimum, should have access to these services to an extent equivalent to those available to the community outside.

C. REGIONAL TRENDS IN DRUG USE

Africa

Reliable and comprehensive information on the drug situation in Africa is not available. The limited data available suggest, however, that cannabis use, notably in West and Central Africa (about 12.4 per cent) is probably higher than the global average (3.8 per cent). The prevalence of use of other substances — except for cocaine, which remains at the global average — is low overall in Africa. A recent survey conducted in Cabo Verde in 2012 found

40 For details see annex on drug use in prisons.
41 National inquiry on the prevalence of psychoactive substance abuse
that 7.6 per cent of the population had used an illicit substance at least once in their lifetime, 2.7 per cent had used an illicit substance in the past year and 1.6 per cent in the past 30 days. Cannabis was the most popular drug (2.4 per cent reporting use in the past year) followed by cocaine (0.2 per cent annual prevalence). The survey also reported common use of a “cocktail” containing crack cocaine and cannabis. ATS use, although at low levels (0.1 per cent lifetime prevalence), seems to be emerging.

In Nigeria, the expert perception is that there has been a large increase in the use of cannabis, with some increase in the use of ATS. According to the national survey on alcohol and drug use in Nigeria conducted in 2009, aside from alcohol, the non-medical use of tranquillizers had the highest annual prevalence (5.5 per cent) among the population aged 15-64 years. The misuse of prescription opioids was also reported to be high and more prevalent than the use of heroin (3.6 per cent annual prevalence of other opioids, and 2.2 per cent annual prevalence of heroin).

High levels of use of other substances were also reported, with annual prevalence as follows: cannabis, 2.6 per cent; amphetamine, 1 per cent; methamphetamine, 1.6 per cent; “ecstasy”, 1.7 per cent; cocaine, 1.6 per cent; and crack, 2 per cent. The prevalence in the last year of people injecting drugs was reported as 1.9 per cent.

In South Africa, expert perception is that there is some increase in the use of heroin and methamphetamine and some decrease in the use of crack cocaine (with use of other drugs being stable).44 Treatment facilities report that cannabis remains the most common illicit substance used, particularly among young people. Almost half of the admissions at specialist treatment centres were primarily related to cannabis use disorders. Polydrug use appears to be a common phenomenon among drug users in treatment.45

Americas

With the exception of opiate use, use of all other groups of substances (cannabis, opioids, cocaine, ATS and “ecstasy”) remains at levels higher than the global average in the region.

North America

In the United States, past-year illicit drug use by persons aged 12 years or older reached the highest level in the past 10 years, increasing from 14.9 per cent in 2011 to 16.0 per cent in 2012. That overall increase in drug use, led mainly by the increase in cannabis use, is considered to be linked with lower risk perceptions of cannabis use, especially among young people.46 The use of cannabis rose from 11.5 per cent to 12.1 per cent and the non-medical use of psychotherapeutic drugs, particularly prescription opioids, rose from 5.7 per cent to 6.4 per cent after declining in 2011. In 2012, use of cocaine also increased slightly among the adult population but remained stable or declined among youth.47 In 2012, drug use was reported to be the highest among those in their late teens or twenties, while drug use among older adults, e.g., among those in their fifties, was also increasing, partly due to the ageing cohort of “baby boomers”, whose levels of drug use have been higher than those of previous cohorts.48

However, past-year use of any illicit substance declined from 19.0 per cent in 2011 to 17.9 per cent in 2012 among the youth population aged 12-17 years, reaching the lowest level in the previous 10 years. From 2011 to 2012, past-year and past-month use of almost all drug types declined

47 United States, Department of Health and Human Services, Substance Abuse and Mental Health Services Administration, Results from the 2012 National Survey on Drug Use and Health: Detailed Tables (Rockville, Maryland, 2013), table 7.2B.
or remained stable among the 12-17 years age group.\textsuperscript{49}

In the United States, the increasing non-medical use of pain relievers (prescription opioids) is also reflected in the continuing increase in the percentage of treatment admissions for opiates other than heroin,\textsuperscript{50} which now surpass treatment admissions for cocaine and methamphetamines.\textsuperscript{51} The number of deaths resulting from prescription painkiller overdose also continues to rise, especially among women.\textsuperscript{52} However, increases in heroin-related overdose deaths in the United States have also been reported (see “The interplay between illicit and pharmaceutical opioid use”). In addition, medical emergencies related to the non-medical use of pharmaceuticals increased 132 per cent over the period 2004-2011, with the number of medical emergencies involving opiates and/or opioids rising 183 per cent.\textsuperscript{53}

In Canada, however, past-year use of cannabis in 2012 among the population aged 15 years or older remained unchanged from the previous year, while there was an increase in cannabis use among those aged 25 years or older: from 6.7 per cent in 2011 to 8.4 per cent in 2012. Past-year use of other illicit substances was estimated at about 1 per cent, and no changes were observed in the prevalence of those substances in the short term (2011-2012) or the long term (2004-2012).\textsuperscript{54}

Latin America and the Caribbean

In South and Central America and the Caribbean, use of cocaine remains high, especially in South America, where cocaine use is currently at levels comparable to high-prevalence regions. With the exception of ATS, the use of other illicit substances remains low in the subregion.

According to a recent survey conducted among university students in the four Andean countries, the annual prevalence of cannabis use ranged between 15.2 per cent in Colombia and 3.6 per cent in the Plurinational State of Bolivia. Cocaine use was high in Colombia (2.2 per cent) compared with 1.1 per cent in Ecuador, 0.5 per cent in Peru, and 0.3 per cent in the Plurinational State of Bolivia. ATS prevalence was reported at 0.9 per cent in Colombia, 0.7 per cent in Ecuador and 0.5 per cent in Peru. Comparing the trends between 2009 and 2012, among students in the four countries there has been an overall increase in cannabis use (from 4.8 per cent in 2009 to 7.9 per cent in 2012), a small increase in the use of ATS and stable trends with regard to cocaine use. A major finding of the survey was the high prevalence of use of lysergic acid diethylamide (LSD) among university students, which increased from 0.2 per cent in 2009 to 0.95 per cent in 2012.\textsuperscript{55} LSD use was reported as being particularly high among students in Colombia.\textsuperscript{56}

Asia

Reliable prevalence estimates are available for only a few countries in Asia. Those data suggest that consumption of illicit drugs is at levels similar to or below the global average. Tentative estimates suggest that cannabis is the most common illicit substance, with an annual prevalence of use of 1.9 per cent among those aged 15-64 years, followed by ATS (excluding “ecstasy”) at 0.7 per cent, “ecstasy” at 0.4 per cent, opiates at 0.35 per cent and cocaine at 0.05 per cent. As reported by experts, the use of methamphetamine continues to rise in most countries in East and South-East Asia, with accompanying seizures of methamphetamine in pill and crystalline forms reaching record levels in 2012. “Ecstasy” use seems to be staging a comeback, while use of new psychoactive substances is on the rise.\textsuperscript{57}

In the absence of reliable survey data, national experts have indicated that in East and South-East Asia, the use of ATS has both increased and diversified. ATS have been ranked among the three drug types most used in countries in the subregion since 2009.

Methamphetamine pills are predominantly used in countries such as Cambodia, the Lao People’s Democratic Republic, Myanmar, Thailand and Viet Nam, whereas crystalline methamphetamine is the primary drug of concern in Brunei Darussalam, Cambodia, Indonesia, Japan, the Philippines and the Republic of Korea.\textsuperscript{58} There has also been a resurgence in the “ecstasy” market, with increased use in 2012 being reported by experts in a number of countries following a decline for several years.

\textsuperscript{49} Ibid., Detailed Tables, tables 7.5B and 7.6B.

\textsuperscript{50} The category “opiates other than heroin” includes non-prescription methadone, buprenorphine, codeine, hydrocodone, hydromorphone, meperidine, morphine, opium, oxycodone, pentazocine, propoxyphene, tramadol and any other drug with morphine-like effects.

\textsuperscript{56} The Colombian forensic experts of the Attorney General’s Office analysed samples of substances sold as LSD, following a reported increase in its use and unusual health effects reported by users. The results from samples obtained in three major cities of Colombia revealed that substances sold as LSD did not contain such substance but rather the synthetic phenethylamines 25B-NBOMe and 25C-NBOMe (reported in UNODC, Global SMART Update 2013, vol. 10, September 2013).

\textsuperscript{57} UNODC, Global SMART Update 2013, Patterns and Trends of Amphetamine-Type Stimulants and Other Drugs: Challenges for Asia and the Pacific (Vienna, November 2013).

\textsuperscript{58} Ibid.
“Ecstasy” seizures more than tripled in 2012 compared with the previous year. The new psychoactive substances market is also growing rapidly in the subregion. Ketamine use has been long-standing in the region. Its use is considered to be stabilizing, while kratom continues to be used as a traditional stimulant in Malaysia, Myanmar and Thailand. The use of synthetic cannabinoids has also been reported in China, Indonesia, Japan, the Republic of Korea and Singapore.59

Experts from China report a stable situation with regard to the consumption of cannabis, cocaine, and tranquilizers and sedatives. However, the number of registered drug users continued to increase. Opioid use remains high in China, with 1.272 million opioid users registered by the end of 2012, compared with 1.18 million in 2011.60 The proportion of heroin users among registered drug users (59 per cent of users) decreased in 2012, as the number of registered synthetic drug users increased more than heroin users, especially because, as reported by the experts, there has been a large increase in the use of methamphetamine.61 Moreover, recent estimates of people who inject drugs — primarily heroin — are lower than previous estimates. The estimated prevalence of people who inject drugs in China, at 0.19 per cent in 2012, is less than the estimate of 0.25 per cent for 2005.62

Compared with East and South-East Asia, South-West and Central Asia are marked by high prevalence of opiate use, with an accompanying high prevalence of people who inject drugs and who are living with HIV: 28.8 per cent in South-West Asia and 7.7 per cent in Central Asia. The prevalence of opiate use in Afghanistan, Iran (Islamic Republic of) and Pakistan is among the highest globally (average of 1.5 per cent of the adult population in the three countries), whereas it is 0.8 per cent in Central Asia — twice the global average.

Europe

In Europe, cannabis is by far the most commonly consumed illicit substance, with an estimated 24 million past-year users (4.3 per cent of those aged 15-64), followed by cocaine with 3.7 million past-year users (0.7 per cent of those aged 15-64). The use of opioids and opiates is comparable to global average levels. ATS (excluding “ecstasy”) are consumed at a level little below the global average, but the use of “ecstasy” is higher, with an annual prevalence of 0.5 per cent compared with the global average of 0.4 per cent. Illicit drug consumption patterns are quite different between the two subregions in Europe. The use of cannabis and cocaine is much higher in Western and Central Europe, whereas the consumption of opioids and opiates is much higher in Eastern and South-Eastern Europe.

Western and Central Europe

In Western and Central Europe, although cannabis use remains high (5.7 per cent annual prevalence), there is evidence of trends of decreasing use, especially in countries with long and established cannabis use.63 The recent household surveys in Poland and Italy show substantially lower prevalence of cannabis use than previously reported, which can also be ascribed to methodological differences in those two most recent surveys.64 There is also an increasing diversity in the types of cannabis products available, especially high-potency herbal cannabis and the synthetic cannabis-like products that are emerging in the subregion.65

Cocaine consumption in Western and Central Europe remains high, at 1 per cent of the adult population. However, countries with high levels of use, e.g., Denmark, Italy, Spain and the United Kingdom of Great Britain and Northern Ireland, report a declining trend in cocaine use as well as in treatment demand.66

The past-year use of opioids, mainly heroin, is estimated as 0.4 per cent of the population aged 15-64. However, in Western and Central Europe, other opioids such as buprenorphine, fentanyl and methadone are available in the illicit markets, with reports that heroin has been

60 China, National Narcotics Control Commission, Annual Report on Drug Control in China 2013 (Beijing, 2013).  
61 UNODC, annual report questionnaire replies submitted by China for 2012.  
64 Use of cannabis in Italy was reported as 14.6 per cent in 2009 and 4 per cent in 2011, while in Poland cannabis use was reported at 9.6 per cent in 2010 and 3.8 per cent in 2012.  
66 Ibid.
replaced with fentanyl and buprenorphine in some countries. Overall, most countries in the subregion report declining trends in the use of heroin. The number of heroin users entering treatment for the first time has also been declining, resulting in an ageing cohort of heroin users currently in treatment. Injecting heroin, a common practice, has also been declining. Coupled with other interventions, this is likely to have contributed to the decline in the number of new HIV infections among heroin users who inject drugs.

Amphetamine and “ecstasy” remain the most commonly used synthetic stimulants in the subregion, with an annual prevalence of use of 0.6 per cent and 0.5 per cent of the adult population respectively. Injecting amphetamine continues to be seen as common among chronic drug-use populations. While amphetamine use has been stabilizing in parts of the subregion, there are concerns that it is being displaced by methamphetamine, given the increasing availability of methamphetamine in some markets.

**Eastern and South-Eastern Europe**

The main concern in Eastern and South-Eastern Europe is the high level of consumption of opioids, notably opiates, with annual prevalence rates of 1.2 per cent and 0.8 per cent, respectively. “Ecstasy” use is also above global average levels, with an annual prevalence of 0.6 per cent. The subregion is also marked by having one of the highest prevalence rates of people who inject drugs, as well as a high prevalence of people who inject drugs living with HIV. In two countries with high rates of opiate consumption, Belarus and Ukraine, experts perceive a significant increase in the use of opiates, with Belarus also reporting a significant increase in the use of opium. Heroin use is reported as stable in Ukraine, and there is an increase in the use of ATS in the country.

The Russian Federation has the highest prevalence of opiate use in the subregion. However, heroin use is reportedly being replaced by cheaper and more readily available prescription or over-the-counter preparations containing opioids. The use of ATS, synthetic opioids and synthetic cannabinoids is also perceived to be increasing, particularly among the youth population.

**Oceania**

Drug use information in Oceania is limited to Australia and New Zealand. No new data are available for 2012. The region has high levels of use of most substances: cannabis, 10.8 per cent; synthetic opioids, 3.0 per cent; cocaine, 1.5 per cent; ATS, 2.1 per cent; and “ecstasy”, 2.9 per cent.

In Australia, expert opinion points to an increase in the consumption of cannabis, cocaine, hallucinogens, and solvents and inhalants, but a decline in the use of “ecstasy”. There is a wide range of drug analogues and new psychoactive substances that are currently available in the Australian illicit drug market.

In New Zealand, experts have reported that there has been an increase in the use of heroin, pharmaceutical opioids, prescription stimulants and synthetic cannabinoids. There has also been a diversification of new drugs available in a wide variety of forms: a range of synthetic drugs sold under the broad product name “ecstasy”, a large number of new synthetic cannabinoids and new analogues of existing controlled drugs and so-called “research chemicals”.

**Drug use and the financial crisis in Europe**

The global financial crisis had, and continues to have, significant effects on joblessness and income inequality, as well as physical and mental well-being. Although
The “dark net”, bitcoins and the increasing sophistication of online drug sales

The online marketplace for illicit drugs is becoming larger and more brazen, now capitalizing on technological advancements in private web transactions and virtual online currency to protect the identities of suppliers, consumers and website administrators. Buyers and sellers are connecting online via “dark net” sites and most often, traffic drugs directly through the postal service. UNODC global seizure data indicate that over the past decade, there was a 300 per cent increase in cannabis seizures obtained through the postal service between 2000 and 2011, the majority of which are coming from seizures reported from countries in Europe and the Americas.

The “dark net” cannot be accessed through traditional web searches; it requires logging in through a web proxy, such as to a Tor3 network, which connects to another location in the network, ensuring that the Internet Protocol (IP) address is not visible on either side of the transaction. These websites do not function as stores per se but work in a manner similar to eBay,4 where users and buyers can connect and are provided a venue to manage transactions and track fraudulent sales. Transactions are mostly conducted using the online peer-to-peer currency “bitcoin”, which remains in escrow, until it is transferred to the seller once the product is satisfactorily delivered. At the time of this writing, 1 bitcoin was worth $625.

Several websites such as “Black Market Reloaded”, “The Armory” and “The General Store”, like the now defunct “Silk Road” website, sell a wide variety of products using this method. Despite the efforts to keep the site administrators, users and sellers unknown, 2013 saw the successful dismantling of several of these large-scale online drug trafficking operations, most notorious among them being the “Silk Road”, which was seized by the Federal Bureau of Investigation of the United States, along with $28 million in bitcoins belonging to the administrator.5

While “Silk Road” sold approximately 24,400 drug products, websites such as “The Armory” have taken over broader elements of weapons and ammunitions trafficking after they were no longer available on the “Silk Road”.6 In a research paper on the user experience of the “Silk Road”, an interviewee, after detailing his favourite purchases (good-quality cannabis, 3,4-methylenedioxymethamphetamine (MDMA), and 2,5-dimethoxy-4-isopropylamphetamine (2C-I)) stated that the “Silk Road” provided users with access to substances they otherwise would not have tried.7

While there are no reliable statistics on how many people are buying drugs on the Internet, the variety available and purchased on the “dark net” appears to be diverse and growing. Because purchases and sales through the “dark net” pose unique challenges for law enforcement and presents a niche market for high-quality drugs and new psychoactive substances, if the past trend continues, it has the potential to become a popular mode of trafficking in controlled substances in years to come.

Data are not yet available to explore the comprehensive impact of the crisis on drug markets, but early information describes two phenomena that have developed in parallel to the crisis: first, the reduction of services provided as a result of decreased funding, and second, a shift from more expensive to cheaper drugs (see below), and increased risk of harm due to the use of substances that require more

---

1 The term “dark net” refers to a distribution network of users, obscured by encryption technology, and anonymized by hidden IP addresses. “Dark nets” are niches within the “deep web”, which includes network connected sites that are not searchable by major search engines.

2 UNODC, individual drug seizure database.

3 “TOR” is the acronym for “The Onion Router” and works by encrypting communications to relay Internet traffic through multiple proxies worldwide to mask users’ locations and hide servers.

4 An online auction and shopping website in which people and businesses buy and sell a wide variety of goods and services worldwide.

frequent injections (see: HIV among people who inject drugs). While surveys on the number of problem drug users in many of the hardest hit countries are not yet available, experts expect the number of dependent users to remain stable.\textsuperscript{81}

**Shifting trends in patterns of drug use**

In some of the countries most affected by the financial crisis, demand for heroin declined, as users shifted to cheaper drugs. For example, between 2008 and 2009 in Milan, Italy, decreases in cocaine and heroin, which are more expensive, were observed, but increases in methamphetamine and cannabis, which are less expensive drugs, were noted.\textsuperscript{82} In Romania, among people who inject drugs, a shift was observed, with 97 per cent interviewed in 2009 reporting heroin as the main drug of injection and in 2012, most respondents (49.4 per cent) reportedly injecting ATS (mostly synthetic cathinones) and only 38.1 per cent injecting heroin.\textsuperscript{83} In Greece, increased injection of a cheap new stimulant-type drug called “sisa”, has been reported. “Sisa” can be made in a kitchen from ephedrine, hydrochloric acid, ethanol and car battery fluid.\textsuperscript{84} Widespread polydrug use also facilitated those shifts.

**Drug-related crime (drug law offences)**

According to available information, during the period 2003-2012, both the number of persons arrested/suspected for possession for personal use\textsuperscript{85} and the number of users of illicit drugs increased: the former group by 31 per cent and the latter by approximately one fifth. Relative to the total population, the rate of persons arrested for or suspected of offences related to possession for personal use increased by 18 per cent, while the point estimate prevalence of drug users (as a percentage of the population in the 15-64 age bracket) has remained fairly stable.

The increases in drug-related crime were also apparent in offences for drug trafficking,\textsuperscript{86} while other kinds of crime declined. Although these indicators come with a large degree of uncertainty, they suggest that, over the period 2003-2012, the annual global proportion of drug users that was arrested for possession for personal use has fluctuated between 3 and 4 per cent. This suggests that the increase in crime rates for possession for personal use was due to the increase in the total number of drug users.

Comparing the relative importance of the various drugs

\textsuperscript{85} Drug possession for personal consumption refers to drug offences related to the use or the possession of drugs for personal consumption (see art. 3, para. 2, of the United Nations Convention against Illicit Traffic in Narcotic Drugs and Psychotropic Substances of 1988).

\textsuperscript{86} Drug trafficking refers to drug offences committed not in connection with the use or possession of drugs for personal consumption (see art. 3, para.1, of the 1988 Convention).
1. RECENT STATISTICS AND TREND ANALYSIS OF THE ILLICIT DRUG MARKET

Fig. 14. Share of the four major drug classes in drug offender records, by region and globally, 2012

Source: UNODC estimates based on annual report questionnaire.

a Since a given offender can be recorded in connection with different drugs, the percentage of records given does not necessarily coincide with the percentage of offenders. In addition, offenders recorded in connection with other substances are not included in the graph. Hence the total may not add up to 100 per cent.

b Average of the five regions, weighted by the estimated number of offenders (for all drug types) in each region.

to trafficking. In other regions, opioids or ATS take second place for possession related to personal use.

In Asia, illicit opioids offer some competition to cannabis as the most prominent drugs for possession related to personal use, and illicit ATS emerge as the most prominent for trafficking offences.

In Europe, illicit ATS ranked last among these four drug classes in terms of trafficking offences, despite being in second place (after cannabis) in terms of personal drug use offences.

An analysis of the gender make-up of persons recorded for drug-related offences indicates that the population apprehended for using controlled substances tends to be predominantly male, in keeping with the picture that emerges from drug use data. The same is true for trafficking. For all drug classes and with respect to both possession for personal use and trafficking offences (separately), less than
one quarter of offenders were female. However, that proportion of female offenders varied significantly for the various drug classes, with the category of sedatives and tranquillizers standing out as the one with relatively high proportions of females, for both possession for personal use and trafficking offences. This conforms with drug use data for women.

The proportion of female offenders tended to be higher for trafficking offences than for possession related to personal use, but typically only marginally so, and still far below 50 per cent. Moreover, the relative importance (ranking) of each drug class, in terms of frequency of offending by females, was quite similar for trafficking and drug-use offences.

**D. OPIATES: OVERVIEW**

**Cultivation and production**

The global area under illicit opium poppy cultivation in 2013 was 296,720 hectares (ha), the highest level since 1998 when estimates became available. An increase in cultivation was seen in both Afghanistan and Myanmar. The main increase was observed in Afghanistan, where the area of opium poppy cultivation increased 36 per cent, from 154,000 ha in 2012 to 209,000 ha in 2013. The main area of cultivation in Afghanistan was in nine provinces in the southern and western part of the country, while the major increase was observed in Helmand and Kandahar.87 In Myanmar, the increase in the area of cultivation was not as pronounced as in Afghanistan. In South-East Asia, the total area under cultivation in the Lao People’s Democratic Republic in 2013 was estimated as 3,900 ha (range: 1,900-5,800 ha). However, the 2013 estimates are not comparable with the estimates of 2012 due to the varying methodology in the use of high-resolution satellite images and time of conducting the helicopter survey.88 Myanmar continued the trend of increasing cultivation that began after 2006.89 (See tables in annex I for details on opium poppy cultivation and production in the different countries and regions).

The potential production of opium in 2013 is estimated at 6,883 tons, which is a return to the levels observed in 2011 and 2008. The opium production in Afghanistan accounts for 80 per cent of the global opium production (5,500 tons). The potential production of heroin (of unknown purity) has also increased to 560 tons, comparable to 2008 estimates of 600 tons (see figure 16).

**Seizures**

Globally, seizures of heroin and illicit morphine went down 19 per cent in 2012. The main declines in opiate seizures were reported in South-West Asia and Western and Central Europe, where seizures declined by 29 per cent and 19 per cent, respectively (from 117 tons in 2011 to 82 tons in 2012 in South-West Asia, and from 6 tons in 2011 to 4.85 tons in 2012 in Western and Central Europe). A substantial increase in heroin seizures, however, was reported in Eastern and South-Eastern Europe (15.98 tons in 2012 compared with 9.88 tons in 2011), mainly as a result of increased quantities reported seized in Turkey. Heroin seizures also increased substantially in Australia and New Zealand (1.09 tons in 2012 compared with 0.61 tons in 2011) and in South Asia (1.3 tons in 2012 compared with 0.723 tons reported in 2011). In North America, heroin seizures declined by 58 per cent in Mexico but increased

89 Ibid.
1. RECENT STATISTICS AND TREND ANALYSIS OF THE ILLICIT DRUG MARKET

in the United States, to 5.5 tons in 2012, compared with 4.8 tons in 2011. However, overall heroin seizures in North America have remained stable over the previous year.

**Extent of use**

Past-year use of opioids, including heroin and prescription painkillers, is estimated at between 28.6 and 38 million people globally. Compared to the global average prevalence of 0.7 per cent, opioid use remains high in North America and Oceania, with prevalence rates of 4.3 per cent and 3 per cent respectively. While opioid use has increased globally over the past year, the main increase has been observed in the United States. Although recent and reliable estimates are not available from Asia and Africa, many experts from countries in those regions also perceive an increase in opioid use. The use of opiates (heroin and opium), however, remained stable globally, with 12.8 million to 20.2 million past-year users. Opiate use at levels much higher than the global average of 0.4 per cent remain in South-West Asia (1.21 per cent), Eastern and South-Eastern Europe (0.82 per cent) and in Central Asia and Transcaucasia (0.81 per cent).

**Opiates: market analysis**

In comparison with other plant-based drugs, the global market for illicit opiates is perhaps the most complex. In contrast to cannabis, illicit cultivation and production feeding the illicit opiate market are limited to certain countries and regions. Consequently, illicit opiates are necessarily trafficked across large distances and through multiple countries in order to meet demand. In contrast to coca bush, illicit cultivation of opium poppy occurs on a significant scale in at least three geographically distinct areas — South-West Asia, South-East Asia and Latin America.
Moreover the historical delineations whereby the supply of illicit opioids in a given consumer market could be assumed to originate in one of those source regions — rather than from several — have blurred, with trafficking routes diversifying accordingly. Moreover, demand for illicit opioids is widespread and cannot be assumed to be concentrated in certain regions. These layers of production and consumption are intertwined. For instance, opium is consumed as is and further used to manufacture morphine, which is then used in the manufacture of heroin. Furthermore, opioids and other opioids, chemically and pharmacologically very similar, are also widely available and used as licit pharmaceutical products, resulting in an interplay that may involve diversion from licit to illicit markets at various stages of the supply chain.

**Long-term assessment**

In spite of the apparent complexity and the fluctuations in key supply indicators, a long-term perspective (taking 1991 as a starting point) reveals some elements of stability in the underlying fundamental indicators at a global level. As of the early 1990s, opium poppy was predominantly cultivated in South-East Asia; following a significant decline in that region, cultivation in Afghanistan increased significantly (reaching a record level in 2013), and cultivation returned to an increasing trend, as of 2007, in Myanmar. Global cultivation reached a low around 2005 and in 2013, returned for the first time to a level comparable to the high level of 1991 (even exceeding it by a small margin). However, owing to the typically higher yields in South-West Asia (disregarding transitory year-on-year fluctuations attributable to environmental factors), the overall trend over the period 1991-2013 was one of increasing production of opium poppy, even if the sharp increase in Afghanistan in 2013 is excluded.

Over the same period, seizures of illicit opioids worldwide (aggregated by assuming a conversion factor of approximately 10 kg of opium per 1 kg of heroin) increased quite steadily. This increase has a significant impact on global supply of opioids. UNODC estimates indicate that the ratio (sometimes referred to as the “interception rate”) of seizures of opioids to illicitly produced opioids present in the illicit market (both expressed in opium equivalents) increased from 4-9 per cent in 1991 to 18-30 per cent in 2012.

With respect to the demand side, the earliest UNODC estimates of global consumption date to the late 1990s. Those estimates have always been produced on the basis of the latest available data, using a methodology that was being continually updated, and are therefore not strictly comparable. Nevertheless, they indicate a generally stable trend in terms of prevalence rate of annual use. However, since the global population has also been increasing, this means that there has been an increase in the number of users. That growth in demand appears to be weaker than the growth in supply. However, the growth trend in supply moves closer to the growth trend in demand once seizures are taken into account. Further, these estimations do not take into account any possible losses that may occur in times of excess production. If such losses did occur, it would suggest that the appropriately adjusted trend in supply would move even closer to the trend in demand. Even without that additional adjustment, and notwithstanding the large degree of fluctuation and uncertainty inherent in these estimates, the available supply of opiates (net of seizures) per opiate user appears to have increased only marginally, if at all, over the period 1998-2012.

Numerically, it would appear that the impact of opiate seizures by law enforcement authorities worldwide, while becoming more discernable in the big picture, had the effect of bringing the apparently strong growth in supply more in line with the growth in demand, which increased more slowly than opium production. However, it is not a foregone conclusion that there is in fact a causal relationship; it could possibly be the outcome of supply adjusting to the circumstances in order to keep meeting demand. In other words, one possibility is that the available supply was contained as a consequence of seizures, but the opposite cannot be excluded: that production adjusted to correct for seizures so as to keep supply stable. Most importantly, this picture is an assessment of the end result, but it is difficult to ascertain, for the purposes of comparison, what would have happened had the efforts of the international community been different. Moreover, it is important to note that the estimates on drug use are based on limited data and therefore subject to a high degree of uncertainty.

**Recent trends**

Although global supply and demand may be evening out globally in the long term, the illicit market for opioids is far from static, especially when shorter-term trends are taken into account. There is growing evidence of significant changes in the flows of heroin out of Afghanistan, of heroin from Afghanistan becoming more available in consumer markets other than the long-established European destinations, and of the interplay between the illicit and licit markets for opioids (including opiates).

**European markets and their relationship to Afghanistan**

It appears that the flow of heroin along the long-established Balkan route, from Afghanistan to Western and Central Europe via Iran (Islamic Republic of) and Turkey, has declined in recent years. Various factors may have contributed to the decline in seizures along this route, including...
1. RECENT STATISTICS AND TREND ANALYSIS OF THE ILLICIT DRUG MARKET

Based on UNODC estimates, the number of past-year users of opiates in Western and Central Europe may have declined by almost one third between 2003 and 2012 (from 1.6 million to 1.13 million). This is also observed, for example, in the data from Germany, where the number of people arrested for the first time for heroin use fell steadily between 2003 and 2012 — overall, by more than one half. Even so, in 2011 and 2012, there may have been a certain deficiency in the available supply of heroin (which may yet be corrected), as the purity-adjusted price of heroin underwent a distinct transition between 2010 and 2011, and maintained the increased level in 2012. Indeed, the decline in heroin flowing on the Balkan Route appears to have been too sudden to be accompanied by a corresponding drop in demand. The ensuing shortfall may have helped trigger the development of routes serving as alternatives to the Balkan route — whose emergence is suggested by other evidence — to supply Europe, possibly via the Near and Middle East and Africa, as well as directly from Pakistan, suggesting that the so called Southern Route is expanding.91

In the replies to the annual report questionnaires for the reporting years 2002-2011, Africa was only sporadically indicated as a region of provenance for heroin reaching Europe; in contrast, in 2012, East Africa which had previously never been identified by a European country as an area of provenance, was among the more prominent such regions in terms of number of mentions, following the Near and Middle East/South-West Asia (including Afghanistan) and South-Eastern Europe (including Turkey). Among East-African countries, the United Republic of Tanzania, which throughout the period 2010-2012 registered annual levels of seizures significantly higher than in previous years, appears to be the most prominent as a country of provenance, although Ethiopia, Kenya and Uganda were also mentioned. Italy in particular appears to be affected by this flow to a significant extent.

In an analysis of 120 cases in the period June 2006-October 2012 in which heroin was seized from air passengers on itineraries involving Europe,92 Pakistan was the second most cited country of provenance, second only to Turkey and followed by Kenya. While the role of Turkey as a transit country appeared to be on the decline over that time period, the cases involving Kenya related almost exclusively to the year 2012. In addition to European countries, other countries from Africa, including East and West Africa, as well as the Near and Middle East, also appeared as countries of provenance in those itineraries.

a Taken as representative of the northern route.
b Taken as representative of the Balkan route.
c Possibly representative of the southern route.

Data from the database on illicit drug seizures with relation to European airports, Germany Customs.
Data on individual heroin seizure cases\textsuperscript{93} from Pakistan up to the first quarter of 2012 also confirm a recently increasing frequency of use of airports in Europe (notably the United Kingdom), the Near and Middle East (notably, in 2012, Oman and Saudi Arabia) and Bangladesh (although that increasing mention of Bangladesh was offset by decreasing mention of other countries in South Asia) as a destination for heroin couriers leaving Pakistan by air. However, consignments trafficked via passenger aircraft are necessarily small, and it is not clear to what extent such trafficking can affect the flow of heroin; these emerging patterns are likely most significant to the extent that they reflect a broader tendency to source heroin from a given region using maritime or land transportation. The number of heroin seizure cases involving sea transport reported by Pakistan was much more limited; however, since 2009 the only such cases with a known destination were predominantly of shipments being sent to West and Central Africa, with all others destined for Western and Central Europe.

A distinct market for heroin, also supplied for several years by heroin from Afghanistan, is that of Eastern Europe,
where the levels of opiate use are significantly higher than the global average. The Russian Federation remains a major consumer market for illicit opiates, with significant quantities of heroin flowing northwards from Afghanistan via Central Asia. A marked increase in total heroin seizures in the Russian Federation and Central Asia together (representative of that northern route) was observed between 1998 and 2004. Since then, overall seizures declined, but it is plausible that the increased availability may have stimulated a demand for opioids, which was met by alternative sources when the influx of heroin subsequently declined. If that is the case, it would be yet another instance of the interaction between the licit and illicit markets for opioids. In 2011 and 2012, in addition to seizures of heroin, the Russian Federation reported seizures of desomorphine — a substitute for heroin that can be derived relatively easily from pharmaceutical products — amounting to 100 kg in 2011 and 95 kg in 2012. Although these quantities are small in comparison with the quantities of seized heroin, in terms of number of cases, in 2012 there was approximately one desomorphine seizure for every three heroin seizures in the Russian Federation. (For comparison, in 2011, there had been approximately three desomorphine seizures for every four heroin seizures in that country.) The fact that the average quantity per seizure of desomorphine was low (8.2 g in 2012 and 3.5 g in 2011, compared with 65 g of heroin in 2012 and 55 g in 2011) confirms that desomorphine is typically home-made and not usually trafficked in large quantities.

### Other markets and new flows through Pakistan

Approximately one fifth of illicit opiate users worldwide live in the subregion of the Near and Middle East/South-West Asia, in spite of the fact that the region accounts for only 6 per cent of the global population aged 15-64 years. Although opiate use, particularly the use of opium, is not new in that region, it is plausible that the high levels of production in Afghanistan may have brought about an increase in the use of opiates (and, by association, possibly other opioids) close to this major source of illicit opium. In Pakistan, the annual prevalence of regular opiate use is estimated to have risen from 0.7 per cent in 2006 to 1.0 per cent in 2013. With reference to the period 21 March

---
1. RECENT STATISTICS AND TREND ANALYSIS OF THE ILLICIT DRUG MARKET

2011-19 March 2012,96 experts in the Islamic Republic of Iran, a country with relatively high rates of opium use, perceived an increase in both opium and heroin use.

With respect to Afghanistan, a recent study97 conducted by the United States Government found high (in comparison with other countries) levels of use or exposure in the urban population of Afghanistan (overall and among both men and women), with 2.6 per cent of the urban test population (of all ages) testing positive for opioids (including pharmaceutical opioids). Users of opioids in the form of opium and heroin were predominantly men, while women predominately used codeine. Even a relatively high proportion of children tested positive for opioid use (including heroin): the study indicates that some 1.3 per cent of urban children were exposed to an opioid present in their physical environment or had been given the drug by an adult.

Although the annual prevalence of use of illicit opiates in East and South-East Asia is estimated to be significantly below the global average, this subregion accounts for approximately one fifth of all users globally, mainly by virtue of the large population of China. In the past, the heroin market in China was supplied mainly from South-East Asia; although Myanmar in particular continues to be a major source country for heroin reaching China, it appears that around 2006, a surplus of heroin from Afghanistan started to find its way to China, via Pakistan and other countries in South-East Asia.98 By 2007, the number of registered heroin users in China, which had declined in 2005, was on the increase, and heroin seizures in China followed a similar pattern, with a slight delay, which could be attributable to a time lag as law enforcement authorities adjusted their efforts to the changing flow. This evidence does not immediately translate into a conclusion that heroin use in China is on the rise, especially since some of these indicators could reflect drug supply and demand reduction efforts rather than supply itself; indeed, the latest UNODC estimates suggest that annual prevalence of opiate use in China (in 2012) is lower than previously thought (0.19 per cent of the general population aged 15-64, compared with 0.25 per cent in 2005). However, it seems clear that the share of heroin in the Chinese market originating in South-West Asia continues to increase, as has also been indicated by Chinese authorities,99 who detected 98 instances of heroin trafficking from South-West Asia in 2012 and 148 cases in 2013.100 Heroin seizures in the Chinese province of Yunnan (bordering Myanmar), continued to increase, reaching 5.4 tons in 2012, constituting 74 per cent of the total for China for that year. It is likely that these quantities originate in Myanmar, in line with the increasing trend in opium poppy cultivation in this country in recent years.

More broadly, South-West Asia (or countries therein) has recently been mentioned as a source of heroin with increasing frequency by countries in South-East Asia, including Indonesia and Malaysia, both of which have registered increasing heroin seizures since 2006. Malaysia in particular has a significant market for heroin, with a relatively high level of heroin use (although declining according to expert perception101), and an increasing inflow of heroin, trafficked via sea and air cargo, facilitated by groups with ties to Pakistan (possibly in collusion with West African groups active mainly in Malaysia in the trafficking of methamphetamine and cocaine) and intended for both the local market and for onward trafficking.102

Nevertheless, the main source for heroin in Malaysia likely continues to be Myanmar.103 In addition to heroin, it appears that the use of morphine is, or at least was in 2010, widespread in Malaysia; moreover, in recent years, authorities have dismantled a number of clandestine laboratories processing heroin (seven in 2011), apparently producing a low purity end product.104,105 The fact that heroin seizures in Pakistan have increased markedly since 2009, independently of the trend in opium production in Afghanistan and in contrast to seizures in key countries along the Balkan and northern routes, suggests a major transformation in the flows out of Afghanistan, with Pakistan playing an important role.

Given the extensive coastline of Pakistan on the Indian Ocean and that maritime channels generally provide the possibility of trafficking large quantities over long distances, it is likely that significant quantities of heroin are trafficked by sea out of Iran (Islamic Republic of) and Pakistan. Seizures by the Pakistan Anti-Narcotics Force (one of several law enforcement agencies in Pakistan) at seaports reached almost 1.2 tons in 2013, more than double the annual amounts throughout the period 2010-2012.106 Reports of individual seizure cases also corroborate

rate those maritime patterns of heroin trafficking. Based on a limited number of officially reported seizures of heroin consignments known to have been trafficked by sea, the proportion of total weight seized in cases for which Pakistan was mentioned as a country of provenance (including seizures made by authorities of Pakistan) rose sharply to a record level in 2009 and since then, has remained higher than in any prior year. In terms of the number of seizures, the increase was more gradual, but the proportion also climbed to record levels in 2010 and 2011. Further information from national law enforcement agencies and international forces on specific, particularly significant seizures in the Indian Ocean, as well as in seaports and coastal regions in Africa, reinforces the evidence that heroin is being transferred for maritime conveyance on the southern coast of Iran (Islamic Republic of) and Pakistan. Laboratory analysis of several large heroin seizures (at least five seizures in excess of 100 kg each) in 2012 and 2013 made by the Combined Maritime Forces in international waters have confirmed that Afghanistan is the country of origin for the heroin trafficked in those cases.

India, with almost 18 per cent of the world’s population in the 15-64 age bracket, is exposed to illicit opiates originating in both South-East Asia and South-West Asia. According to Indian authorities, i.e. country report submitted by India to Thirty-seventh Meeting of Heads of National Drug Law Enforcement Agencies, Asia and the Pacific, and the reply submitted by India in response to the 2011 UNODC annual report questionnaire) heroin from South-West Asia reaches India across the India-Pakistan border and tends to be trafficked onward to destinations such as Europe, the United States and South-East Asia. These destinations are presumably more lucrative markets than India, given the relatively low price of heroin in India (reported to be the equivalent of $8.6-$13 per gram, as of 2011, compared with a range of $100-$400 per gram of heroin from South-West Asia in the United States and an average price, taken from 17 countries in Western and Central Europe and weighted by population, of $72, both in the same year). The share of heroin of South-West Asian origin as a proportion of total heroin seizures in India in 2011 was assessed at 45 per cent, while most of the remainder (54 per cent) originated in India itself (according to information submitted by India in the annual report questionnaire).

Moreover, Indian authorities also indicate illicit cultivation of opium poppy in some pockets within India, suspected diversion of opium from licit cultivation and manufacture of “brown sugar” (also referred to as “low-quality heroin”) on 24 and 25 March 2014.

108 Combined Maritime Forces is a multinational naval partnership that operates in international waters, encompassing some of the world’s most important shipping lanes in the Indian Ocean and adjoining bodies of water.

109 Presentation by the Combined Maritime Forces on counter-narcotics operations in the Indian Ocean, made at the UNODC workshop on Afghan opiate trafficking, March 2014.
Access to pain medication

As stated in the International Narcotics Control Board (INCB) annual report for 2009, “One of the fundamental objectives of the international drug control treaties is to ensure the availability of narcotic drugs and psychotropic substances for medical and scientific purposes and to promote the rational use of narcotics drugs and psychotropic substances”.

While opioids are essential in the management of pain experienced by millions of people who might be suffering from late-stage cancers, AIDS, surgical procedures and other debilitating diseases and conditions, they are also susceptible to abuse. This means that countries face the challenging task of balancing two public health needs: ensuring the availability of these controlled substances for medical purposes and preventing their misuse and diversion.

Many countries have expressed concern about misuse, and available data show a high prevalence of misuse of prescription opioids in some countries. This includes the high-income countries, such as Australia, Canada and the United States that have high per capita consumption of opioids for medical purposes, and even lower-middle-income countries such as Nigeria and Pakistan, which have the lowest per capita consumption of opioids for medical purposes. That suggests that the dynamics of misuse of prescription opioids does not necessarily follow making opioids accessible or available for medical purposes.

As a response to potential or real misuse of these medicines, many countries, contrary to the provisions of the drug control conventions, have laws and regulations that are unduly restrictive or burdensome, resulting in a situation where a large part of the population does not have access to most of the opioid medications commonly used for the treatment of pain and dependence syndrome.

Globally, in 2011, the opioid consumption for medical purposes in morphine equivalence (ME) per person was 61.66 milligrams (mg) per person. This comprises six main opioids: fentanyl, hydromorphone, methadone, morphine, oxycodone and pethidine. However, there is a great disparity among levels of consumption and accessibility of pain medications. The high-income countries, which comprise 17 per cent of the global population, account for 92 per cent of the medical morphine consumed, whereas more than half of the countries that reported to INCB in 2011 had consumption levels of less than 1 mg of morphine per person.

A survey conducted by INCB in 2011 found that the laws and regulations in place for control of pain medications in many countries were unduly restrictive or burdensome and were perceived to be a significant limitation on availability. Other impediments to accessibility to pain medication included insufficient training of health-care professionals in the recognition and management of pain, and economic and procurement impediments such as deficiencies in drug supply management due to low financial resources or low priority given to health care, among other areas.

2 UNODC, discussion paper based on a scientific workshop, entitled “Ensuring availability of controlled medications for the relief of pain and preventing diversion and abuse: striking the right balance to achieve the optimal public health” (Vienna, 2011).
3 Based on the World Bank classification of income levels and development.
4 The annual prevalence of misuse of prescription opioids is as follows: Australia, 3.1 per cent; Canada, 1 per cent; Nigeria, 3.6 per cent; Pakistan, 1.5 per cent; and United States, 5.2 per cent.
5 B. Fischer and others, “Non-medical use of prescription opioids and prescription opioid related harms: why so markedly higher in North America compared to the rest of the world?” Addiction, vol. 109, No. 2 (February 2014), pp. 177-181, and the related debate.

by indigenous groups. Thus, it appears that the consumer market in India is mainly supplied by heroin of domestic origin, quite plausibly derived from a minor proportion of licitly produced opium diverted into the illicit market.

Moreover, heroin originating in India also reaches other countries in South Asia, such as Bangladesh and Sri Lanka, although the flow to Sri Lanka has reportedly declined, and both those countries have long indicated South-West Asia as being among the sources for heroin reaching their territory.

In Africa, aside from its increasing role as a transit area, the number of past-year users of opiates is estimated at between 0.92 million and 2.29 million. That broad range is a consequence of the paucity of data from African countries, which also extends to data from law enforcement authorities. The estimated annual prevalence of heroin use in West and Central Africa is above the global average, those subregions being long associated with small-scale trafficking by air, notably through Nigeria. Based on the latest available responses to the annual report questionnaire, South Africa is also believed to be a major consumer market, deriving its heroin supply from South-West Asia via East Africa and the Near and Middle East.

In Oceania, the annual prevalence of opiate use is relatively low. However, the annual prevalence of opioid use in Oceania is estimated to be more than four times the global average. According to Australian authorities, the number of past-year users of opiates from seizures analysed by the Australian Federal Police were of South-West Asian origin.

According to the United States, in 2012, the availability of heroin continued to increase in that country, likely due to high levels of heroin production in Mexico and Mexican traffickers expanding into “white heroin” markets. Some metropolitan areas in the United States experienced an increase in heroin overdose deaths. Apart from heroin originating in Latin America, heroin from South-West Asia may be reaching the North American market in larger quantities. Canada, which continues to identify Pakistan and India as being among the prominent countries of provenance for heroin reaching its market, mentioned an increase in the number of heroin seizures from couriers on commercial airlines in the latter part of 2012 and in early 2013, and reported that this could be due to a resurgence in the use of heroin across Canada, as well as possible export to other countries, such as the United States. However, the United States has not reported a significant flow of heroin from Canada. India and the United States both indicated that there was a flow of heroin from India to the United States; it is plausible that the flow of heroin reaching North America from India, while probably still small in relation to the size of the North American consumer market, is of South-West Asian origin (as discussed above).

In Latin America, despite illicit cultivation of opium poppy in some countries and the manufacture of heroin in Colombia and Mexico, destined mainly for the United States, the prevalence of opiate use is relatively low. South America, Central America and the Caribbean collectively accounted for less than 3 per cent of global seizures of heroin in 2012.

The interplay between illicit and pharmaceutical opioid use

At the heart of opioid addiction is the powerful rewarding effect that occurs when the active compound binds to the μ-opioid receptor, triggering a cascade of intense pleasurable responses related to the brain dopamine release. Users describe an initial rush followed by feelings of warmth, pleasure and sedation. Once regular use is established, vulnerable individuals develop an uncontrollable compulsive behaviour that is the main characteristic of opioid dependence, seeking to obtain the substance in spite of any negative consequence.

The rewarding effect is progressively modulated by tolerance until a point at which people using the opioid no longer obtain a reward but are aiming to re-establish a “normal” mood. The entire reward system is hijacked by the opioid substance, with motivational reactions no longer being driven by normal life rewards or salient stimuli but by the opioid. Once established, that mechanism is stable and persistent because it is related to significant changes in the expression of the genes of the brain cells.
The use of multiple opioids is common among dependent users, who may choose one or the other depending on factors such as the local accessibility, availability and price of the opioids.

In the United States, where over 5 million people abused prescription pain relievers in 2010, those with the most severe dependency on pharmaceutical opioids were found to be 7.8 times more likely to have used heroin in the past year. In 2012, people in the United States who had ever used heroin were almost five times more likely to have used pain relievers, for other than medical purposes, than people in the general population, and about one third had misused OxyContin, a commercial brand of oxycodone. Conversely, among people who had ever used OxyContin, almost one quarter had also used heroin. Another study compared admissions rates for overdoses from prescription opioids and heroin between the years 1993 and 2009 and found that overdose from one strongly predicted an overdose from the other — evidence that the markets of heroin and prescription opioids are strongly interconnected.

In the United States, the shift in the opioid market towards heroin is also evidenced by high availability and lower prices of heroin. Also, fluctuations in the heroin market, reflected in the price of heroin since 2007, appear to have compensated for the use of other opioids, notably OxyContin, with the price of heroin correlating strongly with the past-month use of OxyContin (see figure 28).

In line with these findings, according to the United States Drug Enforcement Agency, law enforcement officials nationwide have noted prescription opioid abusers switching to heroin because it was cheaper and/or more easily obtained than prescription drugs. Given the variable levels of heroin purity, the replacement of heroin with prescription opioids is also fraught with risks of overdose. In several places in the United States, heroin overdoses have increased substantially. For example, in Minneapolis-Saint Paul, overdoses tripled in the span of one year, rising from 16 overdoses in 2010 to 46 overdoses in 2011.

These changes in the heroin market have been concurrent with national measures to control the misuse of prescription drugs. In 2010, OxyContin was modified to make it a controlled-release formulation so that it could no longer

---

124 United States, Department of Justice, Drug Enforcement Administration, “National Drug Threat Assessment Summary” (November 2013).
be crushed and snorted or injected. Tangible impacts of these measures can also be seen in a study over the transition period (2009-2011), during which OxyContin users were found to be switching to other opioids, including heroin. A United States-based study of 2,566 patients undergoing treatment for opioid dependence before and after the formulation change found that it had led to a decrease in OxyContin misuse among the clients (from 35.6 per cent to 12.8 per cent), but as a replacement, fentanyl and hydromorphone use went up and heroin use had doubled.125

In contrast, the declining availability of heroin in parts of Europe appears to have resulted in an increase in the use of prescription opioids. In Estonia, over the past decade, the local supply of heroin had decreased, resulting in an increase in the use of prescription opioids. Between 2011 and 2012, there was a 38 per cent increase in overdose deaths in Estonia, 80 per cent of which were related to fentanyl and its derivatives.128 INCB now reports that fentanyl and buprenorphine have displaced heroin in Estonia and Finland.129 Similarly, in the Russian Federation, decreased availability of heroin led to its partial replacement with local and readily available substances such as acetylated opium and desomorphine, a home-made preparation made from over-the-counter medicines containing codeine.130

A similar trend can be observed in Australia and New Zealand. In 2001, the heroin market in Australia underwent a supply drop and a consequent change in consumption patterns,131 in which most indicators of heroin use declined and some consumers resorted to prescription opioids as a substitute. In particular, use of oxycodone increased significantly, displacing morphine in some cases.132 A comparison of price data for heroin and oxycodone in Queensland, Australia, in 2011 and 2012 shows that a tablet containing 60 mg of oxycodone cost 20-30 Australian dollars, while an equivalent amount of heroin at retail prices would have cost 40-50 Australian dollars.133 Price data from New Zealand suggest that domestically produced “home bake” — a locally produced substance made from a chemical process involving prescription painkillers — remains a cheaper alternative to costly imported heroin.134

These trends in the overlap of heroin and prescription opioid use can be observed in other regions for which

126 EMCDDA, “Fentanyl in Europe: EMCDDA trendspotter study” (Lisbon, November 2012).
127 Information provided by Estonia in the annual report questionnaire (2012).
limited data are available. In Afghanistan, a survey in urban households showed that over half the women surveyed who reported opioid use (64 per cent) were combining heroin and/or opium with pharmaceutical painkillers, and 9 per cent of opioid-using women used only a prescription opioid.\textsuperscript{135} In recent years, the misuse of tramadol (a lower potency opioid) has also been reported.\textsuperscript{136} in parts of Africa, the Middle East and Asia.

What is clear is that the people who are dependent on opioids will move between the different opioids, interacting one for another, all the while increasing their risks of serious health consequences. However, in the presence of accessible and evidence-based treatment, the situation can be prevented, while supply reduction efforts alone are likely to induce a balloon effect where one controlled substance is replaced by another.

E. COCAINE: OVERVIEW

Cultivation and production

Coca bush cultivation, which remains limited to Plurinational State of Bolivia, Colombia and Peru, continued to decline in 2012 with the net area under coca bush cultivation on 31 December 2012 totalled 133,700 ha, a decline of 14 per cent from the previous year’s estimates and the lowest levels since the beginning of available estimates in 1990. That decline was driven mainly by a 25 per cent decline in coca bush cultivation in Colombia, from an estimated 64,000 ha in 2011 to 48,000 ha in 2012. However, those figures refer to the net area under coca cultivation on 31 December of the year given. In 2012, the Colombian Government manually eradicated 34,486 ha of cultivation and conducted aerial spraying of 100,549 ha. The addition of geographical data available on the presence of coca bush cultivation shows that 135,000 ha had been under cultivation at some point during 2012.\textsuperscript{137} The greatest reduction in coca bush cultivation in Colombia took place in the departments of Nariño, Putumayo, Guaviare and Cauca.\textsuperscript{138} The decline in coca bush cultivation observed in the Plurinational State of Bolivia continued in 2012 (25,300 ha in 2012 compared with 27,200 ha in 2011) and in Peru, where it declined to 60,400 ha from 62,500 ha in 2011. As a result, the estimated global production of cocaine has also declined. In Colombia, the potential production of pure cocaine was estimated at 309 tons, the lowest level since 1996. (For details see tables on coca bush cultivation and production estimates in annex.)

Seizures

Globally, cocaine seizures have slightly increased over the past year, going up to 671 tons in 2012, compared with 634 tons in 2011, driven largely by increased seizures in South America\textsuperscript{139} (418 tons in 2012 compared with 362 tons in 2011) and in Western and Central Europe, another major cocaine market, where seizures increased from 63 tons in 2011 to 71.2 tons in 2012.

\textsuperscript{137} UNODC, Government of Colombia, Colombia: Coca cultivation survey 2012 (June 2013).

\textsuperscript{138} Ibid.

\textsuperscript{139} However, there remains the possibility of double-counting of quantities of cocaine seized, considering that there are joint operations conducted by national agencies together with agencies of other countries.
Extent of use

Cocaine use remained stable over 2012, with 14 million–21 million estimated past-year users globally (0.4 per cent annual prevalence). Cocaine use remained high in North and South America (1.8 per cent and 1.2 per cent annual prevalence rates, respectively), Oceania (1.5 per cent) and Western and Central Europe (1 per cent). While there has been an increase in cocaine use in North America (between 2011 and 2012) due to a number of factors explained below, prevalence of cocaine use in Western and Central Europe declined from an estimated 1.3 per cent in 2010 to 1.0 per cent in 2012.

Cocaine: market analysis

Overall, the latest supply indicators suggest that the global availability of cocaine has fallen in the medium term. However, in 2012, there were signs of a levelling-off or even a possible rebound in some markets. In addition, given that cocaine use is still relatively concentrated in certain markets, there is a certain degree of uncertainty with respect to the extent of the phenomenon in Africa and Asia.

Global cultivation of coca bush is estimated to have fallen by approximately one quarter between 2007 and 2012. However, it is not clear whether the gradual decline brought about a shortage in meeting global demand or represented a return to equilibrium following a surplus around 2007. Indeed, the total area under cultivation, which had been quite stable in the period 2003–2006, at 153,000–157,000 ha, returned to that range in 2010 and 2011. The further decline in 2012 brought the total area of cultivation down to its lowest level since the beginning of available estimates (1990). However, the significance of that recent decline is tempered by the improvements in the efficiency of the cocaine manufacture process that are believed to have taken place over the long term.

Numerous indicators show that the cocaine market in the United States experienced a significant drop in cocaine availability, beginning around 2006, resulting in sustained decreased levels of availability and use. The average cocaine purity (wholesale, retail and overall) as recorded in the System to Retrieve Information from Drug Evidence (STRIDE) database of the United States Drug Enforcement Agency, seizures by the United States Coast Guard and United States authorities along the United States-Mexico border, prevalence of past-month and past-year cocaine use among the general population, the percentage of the workforce testing positive for cocaine based on urinalysis testing, among other indicators, all exhibit turning points in 2005 or 2006.

Cocaine reaching the United States is believed to originate to a large extent in Colombia and to enter the country via Mexico. On the basis of the assessment of the Drug Enforcement Administration of the United States, it appears that, in addition to the decrease in levels of manufacture of cocaine, law enforcement efforts that hindered the activities of Colombian traffickers may have contributed to the reduced availability in the United States, as well as a possibly self-perpetuating cycle of shortages of cocaine and violent conflicts between competing drug trafficking organizations in Mexico. In addition, the marked decline in coca bush cultivation in Colombia in particular may also have contributed to the shortage of cocaine in North America. Cultivation of coca bush in Colombia halved between 2007 and 2012.

In the United States, the trend in some of the cocaine market indicators changed in 2011 and 2012: cocaine seizures rose from 89 tons in 2010 to 106 tons in 2011, and the estimated prevalence of past-year cocaine use in the population aged 12 years or older rose from 1.5 per cent in 2010 to 2.0 per cent in 2012. In terms of the last country from which cocaine entered the United States, Mexico and the countries of Central America collectively accounted for 96 per cent of seizures made in the United States.

140 In its reply to the relevant question in the annual report questionnaire, the United States assessed that 95 per cent of cocaine seized...
1. RECENT STATISTICS AND TREND ANALYSIS OF THE ILLICIT DRUG MARKET

From around 2005 onward, seizures at sea appear to correlate well to a certain extent with the available supply. In between 2006 and 2011, the annual prevalence of cocaine use in the United States shifted upward and 1 year forward. Moreover, the number of first-time users actually declined in 2012, while the trend may be associated with a slight comeback in cocaine availability towards late 2011. However, in 2013 seizures returned to a declining trend, suggesting that only a transitory aberration. Moreover, the increase in past-year use in 2012 appears to have been driven by the consumption patterns of older users, including past users returning to the habit, rather than a predisposition of younger people at risk of initiating cocaine use; indeed, the number of first-time users actually declined in 2012, while the trend in past-year use was increasing only in the older age categories.

South America, long the source of the world’s cocaine supply, has seen an increase in terms of consumption of cocaine (including crack). The number of past-year cocaine users in South America was estimated at almost 2 million in the period 2004-2005 and 3.35 million in 2012. A sig-

Fig. 35. Cocaine retail prices in the United States and Western and Central Europe, 2003-2012

---

142 From around 2005 onward, seizures at sea appear to correlate well with the prevalence of cocaine use, suggesting that maritime seizures reported by the United States reflect cocaine availability reasonably well (significantly better than seizures at the south-west border). When a time lag of one year from the supply indicator (seizures) to the demand indicator (prevalence) is introduced (comparing seizures in the period 2004-2011 to prevalence in the period 2005-2012, rather than using the period 2004-2011), the correlation coefficient improves from 0.80 to 0.96.
significant component of cocaine use in South America is the smoking of various forms of cocaine, including crack as well as other crude forms of cocaine base.

Brazil contains approximately one half of the population of South America; it is a country that is vulnerable to both cocaine trafficking, due to its geography (which makes it a convenient staging area for cocaine trafficked to Europe), as well as to cocaine consumption, due to its large urban population. The last official estimate of annual prevalence of cocaine use in Brazil based on a general population survey dates to 2005. A more recent survey\textsuperscript{143} among college students in Brazilian state capitals estimated the annual prevalence of use of cocaine powder among college students (of all ages) at 3 per cent in 2009.

In Western and Central Europe, supply indicators overall suggest a possible rebound in availability of cocaine. Following a clear decline from the peak of 2006, cocaine seizures reached a low in 2009 at 53 tons and climbed back to 71 tons by 2012. The increase in 2012 was, however, concentrated in a few important transit countries, notably Belgium, Spain and, to a lesser extent, Portugal, while major consumer countries such as France, Germany and Italy registered decreases. However, the retail purity of cocaine increased in some countries with sizeable consumer markets, such as France, Germany and the United Kingdom. Consequently, on the basis of data from 14 countries in Western and Central Europe with relatively good availability of both price and purity data, the estimated weighted average of the purity-adjusted retail price in Western and Central Europe fell significantly, with the equivalent (constant across countries) purity returning to its highest level since 2005.

On the demand side, the data currently available do not indicate any changes in the recent overall decreasing trend in cocaine use in Western and Central Europe; that indication, however, is inconclusive, given that data on use are usually updated less frequently and less promptly than supply indicators such as seizures, prices and purity, and that changes in use may follow changes in availability with a short time lag. The apparent increasing availability in Europe (if confirmed to be real), could possibly be driven by an increasing supply originating in Peru,\textsuperscript{144} and if the trend in use continues to diverge from the trend in availability, it would raise the question of whether a portion of the cocaine entering Europe is possibly destined for emerging markets outside the established markets in Western and Central Europe.

One such possible destination could be Oceania, where the market has expanded in recent years and where prices are higher than in Western and Central Europe. Cocaine seizures in Oceania reached a record of 1.9 tons in 2010, and remained high in 2012, at 1.6 tons. In particular, past-

\textsuperscript{143} Brazil, National Drug Policy Secretariat (SENAD), First Nationwide Survey on the Use of Alcohol, Tobacco and Other Drugs among College Students in the 27 Brazilian State Capitals (Brasilia, 2010).

\textsuperscript{144} The small decline in coca bush cultivation in Peru registered in 2012 was probably too recent to have an impact on indicators in Europe in 2012. As of 2011, cultivation in Peru had increased for six consecutive years (by 34 per cent), while in Colombia it stood at approximately one third less than the peak level of 2007, and in the Plurinational State of Bolivia, where the cultivation area continued to be significantly lower than both Colombia and Peru, it fell to the lowest level since 2005. An increase in cocaine originating in Peru is also borne out by data from Australia (see figure 38 and relevant discussion). See also Cocaine Smuggling in 2011, produced for the United States Office on National Drug Control Policy.

year use of cocaine among the general population aged 14 years or older in Australia rose from 1.6 per cent in 2007 to 2.1 per cent in 2010, although the average frequency of consumption appears to be low, possibly due to the high prices. Indeed, this is corroborated by the fact that Oceania is something of an exception among the major consumer markets, in that both the price and the prevalence are relatively high, while the retail price would be expected to have an inverse relationship to the levels of use, especially when adjusted for purchasing power parity (all other factors being equal).

In terms of the number of cocaine seizure cases in 2012, categorized by country of departure, Australia ranked the Netherlands first and Germany second. It is likely that the majority of those seizures were of small consignments; in terms of weight, and with reference to a slightly different reporting period (July 2011-June 2012), the most prominent European country was the United Kingdom (in fifth place). Moreover, it appears that Peru has increased in importance as a country of origin of cocaine reaching Australia (including possibly through Europe) although, as of mid-2012, Colombia remained foremost among the three producer countries.

In Eastern Europe, seizures of cocaine continue to be limited. Aside from Latin America, countries in Eastern Europe exclusively cited European countries as transit countries for cocaine reaching their territory in 2010-2012. It is likely that the Baltic region serves as an entry point for cocaine entering the Russian Federation. Limited quantities of cocaine may also reach Central and Eastern Europe from the south, via countries in Eastern and South-Eastern Europe, including countries traditionally associated with the Balkan route for heroin entering Europe. The extent of drug trafficking and consumption in Africa is hard to assess. Although seizures in the subregion of West and Central Africa remained below 3 tons in 2012 (including 2.2 tons seized in Cabo Verde alone), cocaine trafficking via West Africa to Europe is believed to be continuing. In 2012, Algeria in particular registered a spike in cocaine seizures, reporting that cocaine transited through countries in West and Central Africa prior to seizure, and identifying trafficking by air as the main mode of transportation. Some of the cocaine may also be diverted to other destina-

146 Finland, Latvia and Lithuania all identified the Russian Federation as being among the destinations of cocaine seized on their territory at least once over the reporting years 2010-2012.

147 This is suggested by a combined analysis of replies to the annual report questionnaire submitted by Albania, Austria, Belarus, Bulgaria, Hungary, Poland, Romania, Serbia, Turkey and Ukraine. See also the *World Drug Report 2013,* pp. 44-45.
tions, possibly including Asia; it is also likely that there is a link with South Africa.148

The estimated prevalence of cocaine use in South Africa rose from 0.78 per cent of the general population in the 15-64 age bracket in 2008 to 1.02 per cent in 2011, confirming the continued existence of a sizeable and apparently expanding consumer market for cocaine. Owing to the paucity of supply-side data, it was not possible to complete the picture of the situation in that country.

Seizures of cocaine in East Africa, while still small on a global scale, have also increased in recent years, notably in the United Republic of Tanzania.

The extent of cocaine use in Asia has always been limited, and the most recent available evidence does not give reason to change that assessment. Nevertheless, cocaine has made its first inroads in this continent, and as pockets of consumption, trafficking and trade in cocaine emerge, factors including affluence149 appear to play a role in determining which countries are affected first. In 2012, the largest aggregate quantities of cocaine seizures in Asia were those seized in Hong Kong, China, followed by the United Arab Emirates and Israel (in that order). The United Arab Emirates, a prominent stopover point for air passenger traffic, has been identified as a transit country by a disparate group of countries with a small, possibly emerging market for cocaine, including countries in Asia and Africa. Israel and Lebanon appear to be destination countries for cocaine, with Jordan and the Syrian Arab Republic serving as transit countries.150 Annual seizures in China and India were below 100 kg in 2011; more significant, relative to the size of the population, were the quantities (each in excess of 25 kg) seized in Japan, Saudi Arabia and Thailand in 2011.

**F. CANNABIS: OVERVIEW**

**Cultivation and production**

Cannabis cultivation remains widespread in most regions, ranging from personal cultivation to large-scale farm and indoor warehouse operations, thus making it difficult to estimate the global levels of cannabis cultivation and production. While cannabis herb is grown in almost every country in the world,151 the production of cannabis resin is confined to only a few countries in North Africa, the Middle East and South-West Asia. In Afghanistan, on the basis of available cultivation and production estimates, in 2012, the total area under cultivation of cannabis was 10,000 ha, down from 12,000 ha in 2011. But potential resin production, due to higher yields per hectare, was estimated at 1,400 tons in 2012, compared with 1,300 tons in 2011. The decline in the price of cannabis resin in Afghanistan between December 2011 and December 2012 supports the assumption of a possible increase in availability over that period.152

---

148 Nigeria identified South Africa as being among the countries of provenance for seized cocaine every year from 2009 to 2012. However, among individual cocaine seizures made in West and Central Africa since 2006, a small number (14) of cocaine consignments (including 9 seized by Nigeria) were seized on their way to South Africa, but none were seized entering the region from South Africa.

149 See also the World Drug Report 2013, p. 40.

150 UNODC annual report questionnaire and other official data.

Among countries reporting in 2012 through the annual report questionnaire, Italy, the United States and Ukraine reported eradication of a large number of plants and cultivation sites.

Seizures

Global cannabis herb seizures in 2012 were reported at 5,350 tons, down from the 6,260 tons reported in 2011. With the exception of the Caribbean and Europe, seizures have declined slightly in most regions. The largest quantities of cannabis herb were seized in North America, which accounts for over 64 per cent of seizures worldwide.

In contrast to cannabis herb, cannabis resin seizures increased in 2012, with 1,269 tons seized, compared with 1,058 tons in 2011. Resin seizures increased significantly in Afghanistan, from 62 tons in 2011 to 160 tons in 2012, and in North Africa (mainly due to increases reported in Algeria (rising from 53 tons to 157 tons) and, to a lesser extent, in Morocco (rising from 126 tons to 137 tons). Spain accounts for 26 per cent of global cannabis resin seizures; although seizures in that country declined slightly from 2011 (356 tons) to 2012 (326 tons).

Based on an analysis of supply indicators for cannabis herb at the retail level (see annex for details), availability remains high in the Americas and appears to be growing in the subregion of Western and Central Europe and in South-Eastern Europe. Despite reports of falling seizures, consumer access to marijuana herb is likely increasing in North America, Oceania, Western and Central Europe and South-Eastern Europe. When retail prices are adjusted by taking into account purchasing power in order to compare prices worldwide, cannabis herb is found to be relatively inexpensive in North America, cheapest in Africa and South Asia (India and Sri Lanka) and most expensive in East and South-East Asia.

As for eradication of outdoor sites and plants, the United States reported a major decrease in sites eradicated (6,470 sites eradicated in 2012 compared with 23,622 sites in...
2011), but it is not known to what extent the decrease was due to declining law enforcement activity in that area or to increasing licit cultivation due to the new cannabis laws in the States of Colorado and Washington. The other countries reporting high numbers of cannabis plants and cultivation sites eradicated are given in the table below.

### Extent of use

In 2012, between 125 million and 227 million people were estimated to have used cannabis, corresponding to between 2.7 and 4.9 per cent of the population aged 15-64 years. West and Central Africa, North America, Oceania and, to a lesser extent, Western and Central Europe remain the regions with prevalence rates considerably higher than the global average. Over the past five years in North America, the largest cannabis herb market, prevalence rates have followed an upward trend in the United States153 but declined in Canada between 2008 and 2011, increasing again between 2011 and 2012.154 Although recent epidemiological data from Asia are not available, experts from nearly half of the countries in Asia consider cannabis use to be increasing in the region.

### Cannabis: market analysis

#### Lower perceived risk and increased harm in consumer markets

Worldwide, the cannabis market (herb and resin) continues to expand, with almost two thirds of reporting countries ranking cannabis as the primary substance of abuse.155 In major consumer markets, treatment enrolment and hospitalizations related to cannabis use have been increasing. In the United States, between 2006 and 2010, there was a 59 per cent increase in cannabis-related emergency department visits156 and a 14 per cent increase in cannabis-related treatment admissions.157,158 Additionally, according to the Potency Monitoring Project of the University of Mississippi, levels of tetrahydrocannabinol (THC) in seized or eradicated cannabis herb crops in the United States increased from 8.7 per cent in 2007 to 11.9 per cent in 2011. Because of the relationship between increased potency and dependence, that trend may be contributing to the increased risk of drug use disorders and dependence.159

155 UNODC, annual report questionnaire for 2012.
Increase in supply of cannabis herb in South-Eastern Europe and Central Asia

With respect to supply measures, although global seizures have declined 24 per cent (from 7,049 tons in 2010 to 5,351 tons in 2012), the market for cannabis herb has become more diversified, with the largest percentage increases in seized herb noted in markets where cannabis resin had previously been predominant throughout Western, Central and South-Eastern Europe. Concomitant with the seizure increases, prices of cannabis herb have increased significantly in South-Eastern Europe and Central Asia. Since 2009, cannabis prices in Turkey have increased the most among all countries reporting worldwide. Increases in herb price were also noted in the region, in Azerbaijan, Kazakhstan, Kyrgyzstan, Greece and Uzbekistan.

Overall, cannabis resin seizures have increased for the third straight year, with decreases in the Americas and Europe and increases in Africa and Asia. Further, the price of resin has also increased in Pakistan, a regional phenomenon potentially related to higher levels of regional interdictions, which is likely resulting in supply shortfalls at the consumer level.

Seizures of cannabis herb now equivalent to cannabis resin in the European markets

There continues to be evidence that cannabis resin is decreasing in popularity in Europe. Whereas cannabis resin had previously dominated the market, now there are nearly equivalent levels of resin and herb seizures, implying a continuing shift away from imported resin coming mainly from Morocco to more locally or regionally produced cannabis herb. Unfortunately, drug use surveys typically do not distinguish between cannabis resin and herb; therefore this cannot be corroborated by drug use data.

Price declines in North America together with higher potency levels

Regarding the cannabis herb market in countries with regu-
latory changes such as the United States and Uruguay, changes in rates of interdiction and in prices are expected. Between 2009 and 2012 in the United States, the price of cannabis herb declined 12 per cent after adjustment for inflation. According to self-reported information on purchases reported to the PriceOfWeed website, since 2010, the price, adjusted for quality, has fallen only 6 per cent, but the price of high-quality cannabis herb has fallen 20 per cent, and the price of medium-quality cannabis herb has risen 40 per cent. Overall, the prices of various qualities of cannabis herb have converged, implying that the price of cannabis herb in the United States has become less variable, indicating more retail market integration.

Changing cannabis policy in the Americas

Recent policy changes to cannabis regulation in Uruguay and in the states of Washington and Colorado now make the authorized production, distribution and consumption of marijuana legal, under some conditions, such as purchasing age. The International Narcotics Control Board has expressed concern that “a number of States that are parties to the 1961 Convention are considering legislative proposals intended to regulate the use of cannabis for purposes other than medical and scientific ones” and it urged “all Governments and the international community to carefully consider the negative impact of such developments.” In the Board’s opinion “the likely increase in the abuse of cannabis will lead to an increase in related public health costs.” Although in those three jurisdictions, the purchase, possession and consumption of cannabis are now legal, the details, design and implementation of the new laws vary significantly. For example, in Uruguay users must register in a database to monitor cumulative purchases (maximum 40 g per month), but in the State of Colorado, purchases of up to 1 oz (28 g) are allowed per outlet, with no central registry of cumulative purchases per buyer nor any limit on the amount that can be purchased each month. Because of these and other notable differences in each law, there is unlikely to be one uniform impact of these policy changes, but rather measurable distinct changes reflecting the contexts of each jurisdiction.

The impact of the new legislation could differ substantially from current cases of depenalization, decriminalization or “medical” cannabis laws by allowing the establishment of a licit supply chain, including large-scale licensing for production, personal cultivation and retail commercialization of the market. While it is not yet clear how the market will change, the commercialization of cannabis may also significantly affect drug-use behaviours. Commercialization implies motivated selling, which can lead to directed advertisements that promote and encourage consumption.

163 UNODC, annual report questionnaire.
164 Price data retrieved on self-reported price, quality and location information for the United States, submitted to the PriceOfWeed.com website.
165 Uruguay, Law No. 19.172. In Uruguay, prior to passing of the new law legislation already exempted from punishment the possession of a “reasonable quantity” (of any drug) intended exclusively for personal use. The new legislation now permits cannabis cultivation, production and sale for recreational use.
167 Data from Amendment 64: Use and Regulation of Marijuana (United States, Constitution of the State of Colorado, art. XVIII, sect. 16). Available at www.fcgov.com/mmj/pdf/amendment64.pdf.
168 The United States federal Controlled Substances Act continues to prohibit cannabis production, trafficking and possession.
169 For non-medical and non-scientific uses.
171 Uruguay, Law No. 19.172.
172 United States, State of Colorado, Amendment 64, sect. 5, part 2.
173 In the states of Colorado and Washington, for-profit businesses can enter the market and use any means that are within the law to promote production, consumption and profits.
For instance, in the case of tobacco companies, advertising was directed to attract new users, which resulted in effective marketing to youth.  

Because laws of this kind have never before been enacted or implemented in a national or state jurisdiction, no previous case studies are available to predict what changes should be expected. Thus, monitoring and evaluation will provide critical data for policymakers. For this reason, it is important that the impacts of this legislation are measured against a number of factors, ranging from the impact on health and criminal justice (effects on the individual as well as institutions and society) to the balance of public revenues against costs and to other social impacts.

At this time, countries and states surrounding Uruguay, Colorado and Washington have not adopted similar regulatory or legislative measures. In consideration of this, additional outcomes that need to be monitored include drug tourism, cross-border leakage and access and availability to youth in neighbouring jurisdictions.

**Health**

While research has not conclusively established the impact of more lenient laws on cannabis consumption, an increase in prevalence of cannabis use from recreational use sales is expected, although it is also possible that the primary effect – particularly in the first decade or so – may differ from longer-term impacts. Expert analyses predict that the legalization of cannabis will most likely reduce production costs substantially, 175 which would in turn be expected to put downward pressure on prices over time, although whether lower prices materialize in the first few years or only in the longer term is unknown. Since cannabis consumption responds to prices, the lower price will probably lead to higher consumption. 176 It is estimated that for each 10 per cent drop in price, there will be an approximately 3 per cent increase in the total number of users 177 and a 3-5 per cent increase in youth initiation. 178

Initiation and use among young and young adults is of particular concern due to the established increased risk of harm, such as other drug use and dependent drug use, a risk of heavy dependence, lung problems, memory impairment, psychosocial development problems and mental health problems, and poorer cognitive performance associated with early initiation and persistent use between the early teenage years and adulthood. 180, 181

For youth and young adults, more permissive cannabis regulations correlate with decreases in the perceived risk of use, 182 and lowered risk perception has been found to predict increases in use. 183

Although it is an important metric to monitor, increases in prevalence of cannabis use may not provide a reliable Services Administration has shown initiation of marijuana use before the age of 15 is associated with higher risk of other drug use at 26 or older, and that those who tried marijuana before the age of 15 were six times more likely to be dependent on an illicit drug at 26 or older (relative to those who initiated marijuana at 21 or older). (See Joseph C. Gfroerer, Li-Tzy Wu and Michael A. Penne, *Initiation of Marijuana Use: Trends, Patterns, and Implications, Substance Abuse and Mental Health Services Administration, Rockville, Maryland, 2002.)

175 Researchers estimate that the pre-tax retail price will decline by more than 80 per cent, but the eventual consumer price will depend on the tax-structure. See Beau Kilmer and others, *Altered State? Assessing How Marijuana Legalization in California could Influence Marijuana Consumption and Public Budgets* (Santa Monica, California, RAND Corporation, Drug Policy Research Center, 2010).

177 Beau Kilmer and others, *Altered State?*

179 Research by the United States Substance Abuse and Mental Health

estimate of the greatest impact on health, since many users use cannabis only occasionally. One aspect to consider is that there is a general, demonstrated increased potency of cannabis in Europe and North America, which may translate into more potent cannabis being available under the new laws and may lead to greater health consequences than in past years (although a clear link between potency and harm has not been conclusively established). Critical areas of harmful use — such as heavy or dependent use, as well as the age of initiation and sustained use — should also be carefully monitored.

Looking at the health impact, it is also important to try to determine if there is a substitution effect whereby cannabis replaces other substances (such as alcohol or more harmful drugs such as heroin) or, conversely, a complementary effect whereby greater use of cannabis leads to greater use of other substances. After drug law reforms in Portugal that decriminalized drug possession for personal use in 2001, referrals for cannabis increased from 47 per cent of referrals in 2001 to 65 per cent in 2005, but referrals for heroin decreased from 33 per cent to 15 per cent, and cocaine remained stable at 4-6 per cent. One study in the United States found that while cannabis-related hospital admissions went up after the decriminalization of cannabis in the period 1975-1978, admissions for other drugs went down.

**Criminal justice**

Criminal justice procedures related to possession for personal consumption are likely to decrease significantly in the context of the new laws, whereas control of other cannabis-related activities, such as cultivation, sale and distribution, will continue to require routine monitoring owing to explicit limitations set forth in the legislation.

The different ways countries have implemented the international drug control conventions determines the extent to which an individual will encounter the criminal justice system for drug possession for personal use, and penalties can range from a warning to more severe consequences, such as incarceration. In countries with depenalization, penalties are reduced or eliminated, but there remains a criminal justice encounter whereby the individual would still face some consequences or rehabilitation. The new legal status of the possession of cannabis in Uruguay and the states of Colorado and Washington means that no such mechanism is provided for.

Over the past decade, across 45 countries, the number of people who have been in contact with the authorities (suspected or arrested) for personal drug use and possession offences has increased by one third (see the section on drug-related crime (drug law offences)). Among these encounters with authorities, cannabis is involved in the majority of cases in every region of the world. There are no data that can show how many of those apprehended were ultimately prosecuted, convicted and incarcerated.

To estimate the overall criminal justice impact of increasingly permissive laws on cannabis is not an easy task. Laws regarding cannabis possession affect both the broader institutional criminal justice system and the individual. For example, a research study in Australia compared, in one area, a group of individuals that received criminal convictions for cannabis offences with a second group of individuals who had been given only infringement notices; those convicted were far more likely to experience adverse employment consequences, recidivism, relationship problems and accommodation difficulties attributed to their offence.

Although it has been mentioned as a rationale for policy change in several cases, the expected impact on the broader criminal networks of drug cartels is unknown. Because so much of cannabis cultivation is local, drug cartels operating in other illicit activities and other drug markets (e.g., cocaine, heroin and methamphetamine) would likely be only modestly affected after cannabis legalization. (Given their population sizes, Uruguay and the states of Colorado and Washington constitute a very small cannabis market).

Although little research is available on the topic, experts estimate cartel losses of nearly $3 billion from the initiatives that passed in Colorado and Washington — with 20-30 per cent cuts in profits. However, in another analysis of the potential impact of cannabis legalization in country in the respective laws and how they are enforced. Decriminalization implies a change in the nature of the consequences of possession or use, from criminal penalties to administrative or civil penalties or to no penalties.

In the United States, approximately 750,000 people are arrested each year for cannabis possession. A similar order of magnitude in the number of arrests is seen in the European Union, with nearly 800,000 arrests for cannabis-related drug offences in 2011.

Robin Room and others, *Cannabis Policy Moving Beyond Stalemate* (Oxford University Press, 2010).

the state of California on Mexican drug trafficking organizations, researchers concluded that legal changes in one state (in this case, California) would not be enough to greatly diminish the market for Mexican cannabis, but if prices dropped significantly nationwide as a result of the spillover to other states, cartel revenue could be affected substantially in the long term. The authors could not unequivocally predict a decline in drug-related violence in Mexico as a result of cannabis legalization, as there was no basis for comparison.195

Economic costs and benefits
Tax revenues from retail cannabis sales may provide significant revenue, although there is uncertainty concerning how much can be raised. In the ballot initiative of Colorado, it was stipulated that tax revenues from the sale of cannabis were to be used to provide $40 million for school construction. Based on assumptions about the size of the market, it was estimated that the ballot measure would bring in as much as $130.1 million in revenue over the period 2014-2015.196 Legalization may also increase income and social security tax revenues by shifting labour from criminal to legal and taxed activities.

However, in Uruguay and the states of Washington and Colorado, significant costs will also be incurred through the establishment of programmes to deter cannabis abuse and regulate the new industry. Based on assumptions regarding the size of the consumer market, it is unclear how legalization will affect public budgets in the short or long term, but expected revenue will need to be cautiously balanced against the costs of prevention and health care.

In addition to the impact on health, criminal justice and the economy, a series of other effects such as consequences related to security, health care, family problems, low performance, absenteeism, car and workplace accidents and insurance could create significant costs for the state. It is also important to note that legalization does not eliminate trafficking in that drug. Although decriminalized, its use and personal possession will be restricted by age. Therefore, the gaps that traffickers can exploit, although reduced, will remain.

The collection of reliable data both before and after these policy changes will support the evaluation of the health, criminal justice and economic consequences of the new regulatory frameworks. Further, careful study of the effects on local and transnational organized crime networks will allow evidence-based decisions to inform policy in this area at the national and regional levels. The impact of this legislation can be evaluated only if it is appropriately measured through reliable data-gathering and regular monitoring efforts.

G. AMPHETAMINE-TYPE STIMULANTS: OVERVIEW

Production, trafficking and consumption
While it is difficult to quantify the global production of ATS, the number of ATS-manufacturing laboratories that were dismantled increased from 12,571 (12,567 ATS labs in addition to four labs producing ATS in conjunction with non-ATS substances) in 2011 to 14,322 in 2012 — nearly all of these (96 per cent) were manufacturing methamphetamine. In North America, methamphetamine manufacturing has expanded again. In 2012, a large increase in methamphetamine laboratories seized was reported by the United States (12,857 in 2012 from 11,116) and Mexico (259 from 159). A significant increase in the number of amphetamine laboratories dismantled in 2012 was reported by the United States (from 57 to 84) and the Russian Federation (from 27 to 38).

For the second year, ATS seizures reached an all-time high of 144 tons, up 15 per cent from 2011, due in large part to increases in methamphetamine seizures. Over the past five years, methamphetamine seizures have almost quadrupled, from 24 tons in 2008 to 114 tons in 2012. Of the total of 144 tons of ATS seized globally in 2012, approximately half were seized in North America alone and approximately a quarter in East and South-East Asia. Large quantities of amphetamine seizures continue to be reported in the Middle East, in particular by Jordan, Saudi Arabia and the Syrian Arab Republic.

Seizures of “ecstasy” have resurfaced after the drop in 2011. Major quantities of “ecstasy” were seized in East and South-East Asia, followed by Europe (South-Eastern Europe and Western and Central Europe). All three regions account for nearly three quarters of global “ecstasy” seizures.

Amphetamine-type-stimulants: market analysis

Diversification and expansion of the global methamphetamine trade
In 2012, methamphetamine accounted for the majority of ATS seizures (80 per cent), approximately 114 tons of the total 144 tons of ATS seized worldwide. Nearly two thirds (64 per cent) of global methamphetamine seizures occurred in North America, and one third in East and South-East Asia. Although Mexico, the United States, China, Thailand and Iran (Islamic Republic of), in that order, continue to report the highest amounts of methamphetamine seized worldwide, there is evidence that methamphetamine trafficking is becoming more global in nature, with notable increases from 2011 to 2012 observed in West and Central Africa (from 45 kg to 598 kg) and Oceania (from 457 kg to 2,283 kg). Growing methamphetamine markets have also been observed in Central Asia and Transcaucasia, as

196 See “The fiscal impact of Amendment 64 on state revenues” (Colorado, Colorado State University, 24 April 2013).
seizures reported increased from less than a kilogram in 2008 to 76 kg in 2012.

In addition, methamphetamine markets grew in South-West Asia, with recent detection of methamphetamine use in Pakistan.\textsuperscript{197}

In North America, methamphetamine manufacturing has expanded again in recent years as evidenced by significant increases in drug and precursor seizures,\textsuperscript{198} with large-scale production in Mexico. Over the past five years, the amount of methamphetamine seized in Mexico increased from 341 kg in 2008 to the equivalent of 44 tons in 2012 (aggregating seizures reported by weight and by volume). The United States continues to seize large quantities, 29 tons in 2012, up from 9.5 tons in 2008. According to the United States Drug Enforcement Agency, approximately half of the seizures in the United States occur at the United States-Mexico border.\textsuperscript{199} After several disruptions to the availability of precursors and the manufacturing processes in Mexico in 2005 and 2007, methamphetamine purity in the United States continued to increase, reaching 93 per cent in the second quarter of 2012. Although the purity of methamphetamine is high, the potency likely decreased following restrictions on precursor access in Mexico (see the box “Does supply control work? Methamphetamine purity and potency following precursor regulations in North America”).

\textsuperscript{197} UNODC and Pakistan, Drug use in Pakistan, 2013.

\textsuperscript{199} United States, Drug Enforcement Administration, “National Drug Threat Assessment Summary” (November 2013).
Seizures of methamphetamine have been surging in East and South-East Asia and Oceania. Between 2011 and 2012, approximately 70 per cent (12 of 17 countries) of the reporting countries in the region noted an increase in seizures of methamphetamine. Although China and Thailand regularly seize the largest amounts, those numbers increased only marginally in relative terms from 2011 to 2012, while the quantity of methamphetamine seized in Australia increased over 400 per cent, from 426 kg to 2,268 kg. Major increases were observed in countries that regularly report smaller numbers of seizures, such as Brunei Darussalam, Cambodia, Singapore and Viet Nam. After a drop in seizures in 2010, Myanmar reported seizures of 2 tons compared with 33 kg in 2011.

Emergence of methamphetamine in South-West and Central Asia

Central Asia is emerging as an ATS market, reporting 253 kg of ATS seizures, 183 kg of which were reported by Kazakhstan. For the first time, in 2012, Tajikistan reported...
seizures of 63 kg of methamphetamine and 21,740 tablets of “ecstasy”. The methamphetamine seized in Tajikistan was from one incident in which customs officials intercepted a large amount shipped from the Islamic Republic of Iran destined for South-East Asia (Malaysia).201

In Pakistan, methamphetamine use was detected for the first time in a national survey, which estimated that approximately 19,000 people (0.02 percent of the population aged 15-64) had used the drug in the past year.202 That marks an emergence of the substance in the area, which had been undetected in prior drug use surveys. According to reports made to INCB203, in the region there have also been increases in seizures of ephedrine, a precursor of methamphetamine. In 2011, India reported over 6 tons of ephedrine seizures, and Iran (Islamic Republic of) reported 3.8 tons.

Amphetamine

Amphetamine continues to dominate the market in the Near and Middle East/South-West Asia, with over 12 tons seized in 2012, representing more than half of global seizures (56 per cent). In the region, the largest seizure totals are those of Saudi Arabia, Jordan and the Syrian Arab Republic, in that order.

In neighbouring Turkey, a shift towards “ecstasy” and methamphetamine trafficking has taken place in recent years, with amphetamine trafficking moving to other markets.

Extent of amphetamine-type stimulant and “ecstasy” use

ATS, excluding “ecstasy”, constitute the second most commonly used group of illicit substances worldwide, with 13.9 million to 54.8 million estimated users. ATS use remained stable in 2010 and 2011, but increased in 2012. Within the different regions, while there is a reported decrease in ATS use in Western and Central Europe, the estimates for North America indicate an increase in ATS use. In the United States, treatment admissions for methamphetamine use were down, and the past-year prevalence has remained stable for the past three years. However, the prevalence of other types of stimulants (amphetamines) has increased (see figure 56), leading to an increase in overall ATS prevalence from 1.8 per cent in 2011 to 2.1 per cent in 2012. The positive rates of urinalysis for amphetamine and methamphetamine among the United States workforce, however, nearly tripled in 2012, reaching the highest levels since 1997.204 An increase in prevalence was reported in Mexico, from 0.02 per cent in 2008 to 0.12 per cent in 2011. While new estimates of ATS use in Asia and Africa are not available, experts from most of the countries in these regions consider ATS use on the rise. Oceania

201 Central Asian Regional Information and Coordination Centre (CARICC) Information Bulletin No. 114, 11 June 2012.
202 UNODC and Pakistan, Drug use in Pakistan, 2013.
203 International Narcotics Control Board annual report 2012 and previous reports.
(2.1 per cent) Central America and North America (1.3 per cent and 1.4 per cent respectively) are the regions with prevalence rates higher than the global average, while the rates in West and Central Africa and Asia remain comparable to the global rates of ATS use.

“Ecstasy”

With between 9.4 million and 28.2 million estimated past-year users in 2012, its use declined globally in the period 2010-2012, mainly in Western and Central Europe. Nevertheless, Oceania (2.9 per cent), North America (0.9 per cent) and Europe (0.5 per cent) remain regions with prevalence rates higher than the global average of 0.4 per cent.

Misuse of prescription stimulants

The misuse of prescription stimulants or medications for attention deficit hyperactivity disorder is not uncommon, although only a few countries report prevalence of misuse among the general and youth population. With the exception of Indonesia, all countries reporting misuse of prescription stimulants are from South and North America. This, however, does not preclude that misuse of prescription stimulants is not common in the other countries or regions. Rather, the detection of such misuse in some countries may be related to better monitoring. The prevalence of misuse of prescription stimulants varies considerably among the few countries reporting, ranging from 3.28 per cent among the general population in El Salvador to 0.1 per cent in Argentina. With the exception of El Salvador, Indonesia and Costa Rica, the misuse of prescription stimulants is higher among men. In El Salvador, the prevalence is 3.7 per cent among women compared with 2.78 per cent among men.

Compared with rates for the general population, countries report a higher level of misuse of prescription stimulants among the youth population (mostly those 15-16 years old). In Costa Rica, compared with the annual prevalence of misuse of prescription stimulants of 1.3 per cent, the rate is nearly 4 times higher among the youth population. A similar pattern of higher rates of misuse of prescription stimulants is seen in the other countries, with the exception of El Salvador, where the prevalence is quite low among youth, 0.2 per cent, compared with 3.28 per cent among the adult population.

Increase in ketamine and mephedrone treatment admissions in the United Kingdom

In the United Kingdom, there has been a decrease in prevalence of ketamine and mephedrone use in England and Wales among both the adult population (aged 16-59) and young adults (aged 16-24).\textsuperscript{201,206} However, there has been an increase in the number of people seeking treatment for ketamine and mephedrone over the past six years. Although users of ketamine and mephedrone account for only 10 per cent of young people in specialist services and 2 per cent of adults in treatment, there are clear signs of an increase in treatment demand for drug use disorders related to club drugs such as ketamine and mephedrone in the United Kingdom. While “ecstasy” remains the most common club drug reported in treatment demand, the number of ketamine and mephedrone users seeking treatment has risen between 2005/06 and 2010/11.\textsuperscript{207}

\textsuperscript{205} The annual prevalence of mephedrone declined from 1.1 per cent in 2011/12 to 0.5 per cent in 2012/13 in the adult population and from 3.3 per cent to 1.6 per cent among young adults, while ketamine annual prevalence has declined from 0.6 per cent to 0.4 per cent in the adult population and from 1.8 per cent to 0.8 per cent among young adults over the same period.

H. NEW PSYCHOACTIVE SUBSTANCES

Update

Of 103 countries for which information on new psychoactive substances was available as of December 2013, 94 countries reported the emergence of such substances on their markets, up from 70 out of a total of 80 countries as of July 2012. This increase was due to reports of the emergence of new psychoactive substances in countries in Europe (9 additional countries), Asia (7 additional countries) and Africa (8 additional countries).

New psychoactive substances are now found in most of Europe and North America, as well as Oceania, Asia and South America and in a number of African countries. The use of new psychoactive substances is thus emerging as a truly global phenomenon. The largest increases in the spread of those substances between July 2012 and December 2013 were reported in Europe (9 additional countries), Asia (7 additional countries) and Africa (6 additional countries).

The number of new psychoactive substances on the global market more than doubled over the period 2009-2013. By December 2013, the number of such substances reported to UNODC reached 348, up from 251 such substances.

Fig. 57. Annual prevalence of misuse of prescription stimulants among youth aged 15-16 years, 2008-2011*

208 This is an update from the World Drug Report 2013, which contains a detailed chapter on new psychoactive substances.

209 Early warning advisory on new psychoactive substances, UNODC.
1. RECENT STATISTICS AND TREND ANALYSIS OF THE ILLICIT DRUG MARKET

Are amphetamine-type stimulants substituting cocaine in the United States?

In the United States, cocaine use has declined but use of amphetamines group substances is on the rise. According to Quest Diagnostics, on the basis of urinanalysis, the number of positives for amphetamine as a metabolite (including, therefore, cases of methamphetamine use, in addition to prescription use and illicit use of amphetamine) among the general workforce in 2012 were the highest since 1997, and positive drug tests for prescription medications such as Adderall more than doubled between 1992 and 2012.¹ Survey data reported over this period for the general population aged 12 or older also indicate a doubling in the past-month use of Adderall, stable use of methamphetamine, and declining use of cocaine since 2007. Taken together, these data indicate that the increase in positive amphetamine tests in the general workforce is likely attributable to prescription amphetamine as opposed to methamphetamine. Indeed, subtracting methamphetamine positives from the total for all positive tests classified as “amphetamine” shows a distinct transition in 2007, when the decline in cocaine began, with the growth rate over the period 2007-2012 being four times that rate over the period 2002-2006. It would appear that the positivity rate for amphetamine now exceeds the historic level reached by the rate for cocaine in the United States in the period 2000-2006. This evidence, although not conclusive, points to the possibility that amphetamines are being used as a substitute for cocaine.

as of July 2012,²¹⁰ and 166 substances in 2009 (see figure 60). Thus, by now, the number of new psychoactive substances clearly exceeds the number of psychoactive substances controlled at the international level (234 substances: 119 controlled under the 1961 Single Convention on Narcotic Drugs and 115 under the 1971 Convention on Psychotropic Substances).

The overall increase over the period August 2012-December 2013 was mostly due to new synthetic cannabinoids (50 per cent of newly identified new psychoactive substances) followed by new phenethylamines (17 per cent), other substances (14 per cent) and new synthetic cathinones (8 per cent) (see figure 61).

Progress has been made in some areas. In the United States, where national controls on some new psychoactive substances were introduced,²¹¹ prevalence of the use of synthetic cannabinoids and of “bath salts” (synthetic cathinones) declined by some 30 percent among high school students. Annual prevalence of synthetic cannabinoid use fell from 11.4 per cent in 2011 to 7.9 per cent in 2013 and prevalence of use of “bath salts” declined from 1.3 per cent in 2012 to 0.9 per cent in 2013 among twelfth grade students.²¹² In England and Wales, annual prevalence of mephedrone, a synthetic cathinone, fell by more than 60 per cent, from 4.4 per cent among those aged

²¹¹ In 2011, mephedrone, methylenedioxypyrovalerone (MDPV) and five synthetic cannabinoids were placed under temporary control (United States, Drug Enforcement Administration, “Schedules of controlled substances: temporary placement of three synthetic cathinones into Schedule I”, Final rule, 21 CFR Part 1308, Docket No. DEA-357). In 2012, these substances, along with 26 synthetic cannabinoids were placed permanently under control within the Controlled Substance Act (as amended by the Synthetic Drug Abuse Prevention Act of 2012).

16-24 years in 2010/11 to 1.6 per cent in 2012/13. While no clear link has yet been established, Government activities aimed at raising awareness among drug users about the health risks associated with new psychoactive substances and the introduction of national controls took place in the same period. Prevalence of use of ketamine, which is also controlled, fell from 2.1 to 0.8 per cent over the same period.

For example, through the Internet website “Talk to Frank” website (www.talktofrank.com) and the Welsh Emerging Drugs and Identification of Novel Substances project (www.wedinos.org).

In 2010, methedrone was initially placed under control as a class B drug in the United Kingdom Misuse of Drugs Act (1971).

Source: UNODC early warning advisory on new psychoactive substances, based on information submitted by Member States and submissions to UNODC from laboratories participating in the international collaborative exercises for national drug test laboratories.
A. INTRODUCTION

A number of strategies have been developed by Member States and the international community over the years to address the world drug problem in a comprehensive way, including demand reduction programmes (prevention, treatment), supply reduction interventions (drug interdiction, dismantlement of drug trafficking organizations, alternative development programmes, eradication) and efforts to control illicit financial flows. A further key intervention in supply reduction has gained importance since the adoption of the United Nations Convention against Illicit Traffic in Narcotic Drugs and Psychotropic Substances of 1988: the control of precursor chemicals, that is, the control of chemicals used to manufacture plant-based and synthetic drugs. As early as the 1990s, the Chemical Action Task Force pointed out that “the procurement of chemicals necessary to manufacture drugs is one of the few points where ... drug trafficking intersects with legitimate commerce. Regulation of legitimate commerce to deny traffickers the chemicals they need is one of our most valuable tools in the battle against drug criminals.”

This has become even more relevant over time, as a growing proportion of the illicit drugs found on the market nowadays are synthetic drugs for which traditional supply-control measures applied to plant-based substances, such as alternative development or eradication, cannot be used.

Progress has been made with regard to precursor control. Such progress has been strengthened through resolutions of the Economic and Social Council and the Commission on Narcotic Drugs, as well as the Political Declaration adopted by the General Assembly at its twentieth special session, in 1998, and the Political Declaration on International Cooperation towards an Integrated and Balanced Strategy to Counter the World Drug Problem, adopted by the Assembly in 2009, and their related action plans and the work done by the International Narcotics Control Board in assisting Member States in monitoring licit trade and preventing diversion.

Nonetheless, chemicals are still available for the illicit manufacture of drugs. Precursor control is a complex area involving a large number of substances which have widespread legitimate uses and which can be easily substituted. It involves many players and multiple links between the licit and illicit sectors.

The present chapter will start with a review of the evolution of licit production and trade in chemicals, the degree of international interdependence and the development of the regulatory framework. It will then analyse the effect of precursor control on the supply of illicit drugs and new challenges, such as the growing role of the Internet, the emergence of substitute precursors, pre-precursors and new psychoactive substances, to which the current controls at the international level do not apply. The pages ahead will present an analysis of the various aspects of precursor control, covering both the licit and the illicit side of this sector while keeping an underlying focus on drug control.

B. WHAT ARE PRECURSOR CHEMICALS?

The term “precursor chemicals” broadly refers to chemicals that are employed in the manufacture of drugs. From a scientific point of view “precursor chemicals” are defined as the chemical substances that become incorporated, at the molecular level, into a narcotic drug or psychotropic substance during the manufacturing process. They can be distinguished from other chemicals used in the manufacturing process, such as “reagents” and “solvents”.

This scientific distinction does not entail legal consequences, however. Article 12 of the 1988 Convention, the legal basis for precursor control at the international level, does not make any such distinction and speaks only of “substances frequently used in the illicit manufacture of narcotic drugs or psychotropic substances”.

In the Political Declaration adopted by the General Assembly at its twentieth special session, in June 1998, and the related measures to enhance international cooperation to counter the world drug problem, the term “precursors” was broadened to encompass all chemicals that are controlled under the 1988 Convention.

2 Progress made in precursor control was highlighted in the March 2014 joint ministerial statement of the high-level review by the Commission on Narcotic Drugs on the implementation by Member States of the Political Declaration and Plan of Action on International Cooperation towards an Integrated and Balanced Strategy to Counter the World Drug Problem.
3 The International Narcotics Control Board is given the prime responsibility for precursor control at the international level under article 12 of the 1988 Convention.
5 “Reagents” are chemicals that react with, or take part in the reaction of another substance during the manufacture of a drug. They do not become part of the molecular structure of the end product. “Solvents” are liquid chemical substances used to dissolve or disperse one or more substances. They do not “react” with other substances and are not incorporated into the molecular structure of the end product. They are typically used to purify the end product.
6 General Assembly resolutions S-20/4 A-E.
C. THE POTENTIAL VULNERABILITY OF THE CHEMICAL INDUSTRY TO THE DIVERSION OF PRECURSOR CHEMICALS

1. Trends and patterns in the production of chemicals

Over the past century, the chemical industry has been one of the main economic growth sectors, and it continues to grow strongly, both in volume and in geographical terms, involving an ever larger number of players. Asia has become the new centre for manufacture, and the increasing number of intermediaries provides greater opportunities for diversion.

The total number of “establishments” in the chemical sector rose worldwide from approximately 61,000 in 1981 to 67,000 in 1990, 83,000 in 2000 and close to 97,000 in 2010. This reflects an expansion of the production base of chemicals and thus potentially expands the possibilities for the diversion of chemicals. This is exacerbated by a growing number of “chemical operators” who are also involved in the trade of such substances.

Data from the United Nations Industrial Development Organization (UNIDO) suggest that chemicals are now being manufactured in most countries. Of the 148 Governments that reported manufacturing output data to UNIDO over the 1990-2010 period, 142 also declared production of chemicals.

The rapid expansion of the chemical sector can also be observed in terms of output. The production output of the chemical industry, expressed in constant United States dollars, almost doubled between 1990 and 2010, and rose more than fourfold between 1960 and 2010 to approximately $3,800 billion (see figure 1).

The “value added” of the global chemical industry, which can be directly compared with the notion of gross domestic product (GDP), shows an increase in constant 2010 dollars from $620 billion in 1990 to about $1,110 billion in 2010. This growth was larger than the growth of the entire manufacturing sector and global GDP (see figure 2). As a result, the proportion represented by the chemical sector in the overall value added of manufacturing increased from less than 11 per cent in 1990 to close to 13 per cent by 2010. Expressed as a percentage of global GDP, the value added of the chemical industry accounts for about 2 per cent, which is comparable to the value added of agriculture, which accounts for 3 per cent of global GDP.

The observed stronger growth of output (5.8 per cent annually during the 2000-2010 period) as compared with value added (3.5 per cent) in the chemical industry (see figure 3) suggests a trend of companies redefining their core products and spinning off non-core production and services to new companies. This can be explained by a reduced vertical integration of the chemical industry, mainly as a consequence of the emergence of new production sites in developing countries. One side effect of this has been increased intra-industry trade in chemicals between continents, which increases the risk of diversion of chemicals used in the clandestine manufacture of drugs.

While the chemical sector has been growing over the past few decades, it is still characterized by some geographical concentration and by significant shifts in production,
C. The potential vulnerability of the chemical industry to the diversion of precursor chemicals

which has implications for precursor control. Traditionally, most chemicals have been produced in Europe and in North America (United States of America, Germany, France and the United Kingdom of Great Britain and Northern Ireland) and — after World War II — the former Union of Soviet Socialist Republics. Initially, only one Asian country — Japan — was included among major chemical producers.

Over the past few decades, however, a number of countries in Asia (notably in East, South and South-East Asia) have gained market share at the expense of North America and Europe (see figure 4). By 2010, Asia accounted for 35 per cent of the global value added of manufacture of chemicals, up from 21 per cent in 1990. China advanced from generating the eighth-largest value added of chemicals in 1990...
to second place (following the United States and ahead of Japan) in 2010. India progressed from fourteenth place in 1990 to fifth place by 2010, following Germany and ahead of Brazil and Mexico.

An analysis of long-term output trends for the chemical sector reveals similar patterns (see figure 5). Above-average growth rates were reported in particular in Asia, notably in East, South and South-East Asia, and output growth accelerated further during the 2000-2010 period. By 2010, China reported the world’s largest chemical industry output, ahead of the United States, Japan, Germany, France, Brazil, the Republic of Korea, Italy, India, the Netherlands, the United Kingdom, the Russian Federation and Switzerland (in that order). The production output of these 13 countries accounted for more than three quarters (78 per cent) of the global output of the chemical industry.

The importance of Asia’s chemical industry as measured in terms of output (44 per cent, see figure 6) exceeds its importance in terms of value added (35 per cent, see figure 4). The opposite is true for the Americas and Europe. This suggests that chemical mass products are increasingly being produced in Asia, while there is still a concentration of some value-added intensive production of chemicals in North America and in Western and Central Europe.

Data on the sales of the chemical industry for 2011 (€2,744 billion, or $3,822 billion) suggest that by that year 52 per cent of global turnover was credited to companies in Asia (see figure 7). Taken together, Asia, Europe and North America accounted for 92.5 per cent of world chemical sales in 2011. The largest sales were reported by companies in China (27 per cent), followed by the European Union (20 per cent), the United States (15 per cent) and Japan (6 per cent). The single largest European producer was Germany (5.7 per cent of global sales). The largest producer in Latin America was Brazil (3.2 per cent), although its sales still lagged behind Asia’s third largest producer, the Republic of Korea (4.3 per cent). Other important producers included France (3.0 per cent of global sales), Taiwan Province of China (2.2 per cent),15 the Russian Federation (2.1 per cent) and the Netherlands (1.9 per cent).16

All of these production shifts have potential implications for the control of precursor chemicals. A chemical industry concentrated among big companies facilitates the control of chemicals that can be diverted for the illicit manufacture of drugs, while a more scattered production system increases the number of trade lines and, ultimately, the risk of diversion. Control systems were initially developed mostly in North America and in Europe, where the chemical industry was dominated by large, vertically integrated companies. This facilitated national controls, including through voluntary cooperation with the authorities. The emerging chemical industry in Asia, in contrast, is charac-

---

13 This ranking is based on UNIDO data for 2010 or the latest year available (adjusted for inflation).
15 Despite its sizable chemical industry, Taiwan Province of China does not participate in international precursor control. The International Narcotics Control Board encouraged the Government of China to work with Taiwan Province of China to devise practical ways and means of addressing the issue, notably in the areas of pre-export notifications, suspicious shipments and diversions of precursors involving Taiwan Province of China (see Precursors Report, 2013, paras. 33).
C. The potential vulnerability of the chemical industry to the diversion of precursor chemicals

WORLD DRUG REPORT 2014

2. Trends and patterns in international trade in chemicals

Growth in international trade in chemicals outstripped growth in the global production of chemicals. While output doubled between 1990 and 2010, chemical exports, expressed in constant 2012 United States dollars, grew to more than three-and-a-half times the size (see figure 8). This pattern became even more pronounced during the 2000-2010 period (see figure 9).

As a consequence, global chemical exports rose from representing 25 per cent of the global output of the chemical industry in 1990 to 33 per cent in 2000 and 43 per cent in 2010. With ever more chemicals being traded among an increasing number of countries, the possibility of diversion of chemicals has increased.

The chemical industry is widely seen as one of the most globalized of all manufacturing industries, and this globalization is still in progress, facilitated by reduced import duties as a consequence of several rounds of the General Agreement on Tariffs and Trade and the subsequent work of the World Trade Organization. Although the value added generated by the chemical industry accounted for “just” 1.9 per cent of global GDP in 2010, the proportion that chemicals comprise of global exports is almost six times as high — and rising (see figure 10).

The relationship between the production and trade of chemicals is not linear. Countries with high levels of production are not always the biggest exporters of chemicals, and almost a quarter of countries have larger chemical exports than domestic production. A more linear corre-

17 The average output per “establishment” of the chemical industry during the 2007-2009 period amounted to $81 million in the Netherlands, $64 million in Belgium and $59 million in Germany. This was more than three times the average output per establishment in China ($18 million), more than eight times the average output per establishment in India ($7 million), 15 times the average in Hong Kong, China, or Viet Nam ($4 million) and more than 40 times the average in Thailand ($1.25 million in 2006) (INDSTAT 2 database).

relation is observed between the levels of exports and imports of chemicals (see figure 11), which underlines the importance of re-exports and the fact that trade flows are not always directly from producing to consuming countries, but instead involve an increasing number of brokers and other intermediaries in the supply chain. Not only does this provide more opportunities for diversion, it makes the effective application of the “know your customer” principle more difficult to achieve.

D. RESPONSE OF THE INTERNATIONAL COMMUNITY

The idea of controlling precursors as one of the strategies for controlling the overall manufacture of drugs and thus their consumption (for non-medical purposes) dates back to the early 1930s. It was only in the late 1980s, however, that an effective international precursor control system was devised. That system was further strengthened over the following decades.

1. Conventions concluded under the auspices of the League of Nations

The basic idea of precursor control was already present in the Convention for Limiting the Manufacture and Regulating the Distribution of Narcotic Drugs of 1931, which had provisions for the international control of a limited number of “convertible substances”, i.e. substances that could be converted into a product capable of producing addiction.

---

21 The “know your customer” principle, for those who manufacture or market chemicals, is set out in the Political Declaration adopted by the General Assembly at its twentieth special session and the measures to enhance international cooperation to counter the world drug problem (General Assembly resolutions S-20/4 A-E).

22 Any product obtained from any of the phenanthrene alkaloids of opium or from the ecgonine alkaloids of the coca leaf.

23 Article 11 of the 1931 Convention made it clear that no manufacture or trade in such products should be allowed “unless and until it has been ascertained to the satisfaction of the Government concerned that the product in question is of medical or scientific value.”
Another reference to the need for precursor control can be found in the Convention for the Suppression of the Illicit Traffic in Dangerous Drugs of 1936. That Convention introduced an obligation to seize such precursors and contained penal provisions for the manufacture, conversion, extraction and preparation of drugs,\(^{24}\) which also had an impact on the handling of precursor chemicals. Both Conventions were superseded by the Single Convention on Narcotic Drugs of 1961.

2. Single Convention on Narcotic Drugs of 1961

A general reference to precursor control, asking for the "supervision"\(^ {25} \) of such substances, is also found in the Single Convention on Narcotic Drugs of 1961 as amended by the 1972 Protocol, which is still in force today. In addition, it allowed substances "convertible into a drug" to be scheduled.\(^ {26} \) The 1961 Convention also obliged parties to seize precursor chemicals and to introduce penal provisions for the illegal manufacture, extraction and preparation of such drugs.\(^ {27} \)

The requirements relating to the introduction of precursor control were broadened in the Convention on Psychotropic Substances of 1971 to include chemicals used in the manufacture of psychotropic substances.\(^ {28} \) Precursors were thus in principle under international control, with provisions for such substances to be seized and confiscated. There was a general obligation for taking "measures of supervision" regarding such substances, though much was left to the discretion of Member States. Thus, only a few countries introduced a comprehensive control regime. Moreover, the 1971 Convention did not include a provision for the scheduling of specific substances that were convertible into a psychotropic substance.\(^ {29} \) This changed only with the 1988 Convention.

4. United Nations Convention against Illicit Traffic in Narcotic Drugs and Psychotropic Substances of 1988

(a) The basic control system

The United Nations Convention against Illicit Traffic in Narcotic Drugs and Psychotropic Substances of 1988 enjoys nearly universal adherence\(^ {30} \).

The basic idea of the Convention is to regulate the trade of a number of chemicals which can be used for the manufacture of drugs by allowing their trade for licit purposes and prevent their diversion for illicit manufacture of drugs. The 1988 Convention establishes a legal basis for the control of precursors and calls for the establishment of an appropriate administrative framework, working mechanism and standard operating procedures to prevent the diversion of such substances. There are hundreds of chemicals that are or could be used in the manufacture of illicit drugs. Of those, a total of 23 chemicals were internationally controlled under the 1988 Convention as of January 2014: 15 substances under the stricter rules foreseen for substances in Table I (for which pre-export notifications are foreseen) and 8 under the less stringent rules for substances in Table II.\(^ {31} \) This list is regularly updated. The
total number of controlled chemical substances in Table I and II nearly doubled from 12 in 1988 to 23 by 2013. The increase over the past two decades has been most noticeable for substances in Table I, rising from 6 in 1988 to 16 following the decision of the Commission on Narcotic Drugs in March 2014 to add alpha-phenylacetoacetonitrile (APAAN) to Table I.

Paragraph 1 of article 3 of the 1988 Convention requires parties to establish as criminal offences the manufacture, transport and distribution of the listed precursor chemicals in the knowledge that they are to be used in or for the illegal cultivation, production or manufacture of drugs.

As in the 1961 and 1971 Conventions, the 1988 Convention requires States parties to take appropriate measures to prevent the diversion of precursor chemicals.

Article 12 lays down more specific control measures for the manufacture and distribution (e.g. licensing, prevention of the accumulation of large stocks) and international trade in precursor chemicals (e.g. notification of suspicious shipments, seizures, proper labelling and documentation, establishment of a comprehensive monitoring system, including pre-export notifications for substances in Table I) while guaranteeing Member States a high degree of confidentiality and limiting controls (e.g. exclusion of pharmaceutical preparations from controls).

### (b) Role of the International Narcotics Control Board

The 1988 Convention also clarified the roles of the various actors. The primary role of precursor control lies with the individual Member States; the International Narcotics Control Board was given the prime responsibility for precursor control at the international level.

The Board is responsible, along with States parties, for recommending to the Commission on Narcotic Drugs the scheduling or rescheduling of chemical substances to be controlled at the international level. While the World Health Organization (WHO) plays a key role in the scheduling of narcotic drugs and psychotropic substances under the 1961 and 1971 Conventions, the Board was given this role for precursor chemicals. It also collects statistics relating to precursors, reports on progress made in precursor control and the normal conduct of business and the prevailing market conditions.

34 Article 12, paragraph 9, lists the following measures that each party shall take with regard to international trade in substances in Table I and II:
(a) Establish and maintain a system to monitor international trade in such substances in order to facilitate the identification of suspicious transactions;
(b) Provide for the seizure of any such substance if there is sufficient evidence that it is for use in the illicit manufacture of a narcotic drug or psychotropic substance;
(c) Notify, as soon as possible, the competent authorities and services of the parties concerned if there is reason to believe that the import, export or transit of such a substance is destined for the illicit manufacture of narcotic drugs or psychotropic substances;
(d) Require that imports and exports be properly labelled and documented;
(e) Ensure that documents referred to in subparagraph (d) above are maintained for a period of not less than two years and may be made available for inspection by the competent authorities.

35 Article 12, paragraph 10, contains the core principle of international precursor control: the obligation of an exporting country, if asked by an importing country, to issue a "pre-export notification" for substances listed in Table I. This then entails some form of a clearance or permission to be granted from the competent authorities of the importing country. Importing countries can adopt stricter measures and request a pre-export notification only for substances in Table I but also for some or all of the substances in Table II. A number of countries have made use of this provision.

36 See article 12, paragraph 11.

37 Article 12, paragraph 14, for example, excludes pharmaceutical preparations from precursor controls if such substances cannot be easily used in the manufacture of drugs. "The provisions of this article shall not apply to pharmaceutical preparations, nor to other preparations containing substances in Table I or Table II that are compounded in such a way that such substances cannot be easily used or recovered by readily applicable means".

38 In the case of States members of the European Union, the prime responsibility is with the European Union, not the individual member States.

39 See article 12, paragraphs 2-7.
D. Response of the international community

Moreover, the Board has been given a special role in monitoring the implementation of precursor control measures by Member States in accordance with the requirements of the 1988 Convention. The potential sanctions of the Board are limited, however, to bringing an issue to the attention of the parties, the Economic and Social Council and the Commission on Narcotic Drugs; it is then up to these bodies to deal with the issue. This is in contrast to the broader powers given to the Board (e.g. recommending an “import ban”) in cases of non-compliance with the other drug conventions.

In addition to collecting data and preparing reports to alert policymakers about new trends, the Board also engages in operational activities. It assists Member States in conducting joint law enforcement operations under the banner of Project Cohesion (with regard to chemicals used in the manufacture of plant-based drugs) and Project Prism (with regard to chemicals used in the synthesis of synthetic drugs) to detect unlawful precursor shipments. In response to various action plans and resolutions, the Board established and maintains a limited international special surveillance list of non-scheduled substances for the identification of substitute chemicals used in the illicit manufacture of drugs. It has also issued the Guidelines for a Voluntary Code of Practice for the Chemical Industry, and established the Pre-Export Notification Online (PEN Online) system, as well as the Precursors Incident Communication System (PICS), a secure online tool to enhance real-time communication and information sharing between national authorities.

5. Resolutions passed by the General Assembly, the Economic and Social Council and the Commission on Narcotic Drugs

Following the adoption of the 1988 Convention, a total of 36 resolutions relevant to precursor control were passed by the General Assembly, the Economic and Social Council and the Commission on Narcotic Drugs during the 1991-2013 period. While some of those resolutions were geared towards simply raising awareness, others were very focused, dealing with specific aspects of precursor control.

6. Political Declaration and Action Plan adopted by the General Assembly at its twentieth special session

Precursor control received a new impetus from the Political Declaration adopted by the General Assembly at its twentieth special session, in 1998, and the related measures to enhance international cooperation to counter the world drug problem, which contained separate resolutions on the Action Plan against Illicit Manufacture, Trafficking and Abuse of Amphetamine-type Stimulants and their Precursors and on the control of precursors.

In its resolution S-20/4 B, on control of precursors, the General Assembly asked Member States to implement many of the proposals made under the 1988 Convention. Member States were requested to adopt and implement the “proposals” of article 12 of the 1988 Convention, including the establishment of a system of control and licensing of the enterprises and persons engaged in the manufacture and distribution of substances listed in Tables I and II of the 1988 Convention. Similarly, exporting States were requested to issue pre-export notifications for substances in Table I to the competent authorities in importing countries (irrespective of whether an importing country had requested such a notification). In addition, information exchange (from data on licit manufacture to imports and exports) was highlighted as being crucial for precursor control, as was strengthened cooperation with associations of the chemical trade and industry which could be achieved by issuing guidelines and/or a code of conduct.

Most importantly, the principle of “know your customer” was introduced at the international level. It obliges the seller of precursor chemicals to investigate the credentials of the purchaser and, if in doubt, to involve the authorities.
In addition, the document highlighted the challenges arising from the use of “substitute chemicals”. In that context, it proposed to prepare a limited international special surveillance list of substances currently not in Tables I and II of the 1988 Convention. This was subsequently implemented by the Board. Moreover, States were asked to apply monitoring measures, in cooperation with the chemical industry, so as to prevent the diversion of substances included on the special surveillance list. In addition, States were asked to “consider punishing, as a criminal offence … the diversion of non-scheduled chemical substances with the knowledge that they are intended for use in the illicit manufacture of narcotic drugs or psychotropic substances”.51

7. Political Declaration and Plan of Action of 2009

Precursor control also played a role in the 2009 Political Declaration and Plan of Action on International Co-operation towards an Integrated and Balanced Strategy to Counter the World Drug Problem. The Plan of Action underlined the need for “a global approach in order to … prevent the diversion of synthetic drugs and their precursors into illicit channels in all manufacturing, transit and consumer countries” and, in the Political Declaration, States Members of the United Nations decided to establish 2019 as a target date for States “to eliminate or reduce significantly … the diversion of and illicit trafficking in precursors”.52

The 2009 Plan of Action shows how the precursor market had changed over time. It recognized that pharmaceutical preparations and chemicals not under international control were being substituted for controlled precursors.53 To respond to these new challenges, the Plan of Action invited Member States to expand the use of pre-export notifications to non-scheduled substances and pharmaceutical preparations. Furthermore, Member States were asked to “develop systems (for example, shared online recording systems) to prevent precursor chemicals from being diverted into illicit channels from community pharmacies”.54

While acknowledging that regulatory controls helped to prevent the diversion of precursor chemicals from international trade, the Plan of Action identified the new problem of precursors being diverted “from domestic distribution channels” in countries where they were manufactured or imported.55

Responding to this new challenge, the Plan of Action asked Member States to “increase efforts, beyond international trade controls, to prevent the diversion of precursors, and pharmaceutical preparations containing the precursors ephedrine and pseudoephedrine, from domestic channels to be smuggled across borders.”56

Another new element is the invitation to Member States to “consider ‘marking’ certain chemical shipments for possible future use if scientific advances ensure the appropriate use of such tools, taking into account the potential burden this would place on authorities and industry.”57

E. PATTERNS AND TRENDS IN PRODUCTION OF, AND TRADE AND TRAFFICKING IN PRECURSOR CHEMICALS

1. Licit activities

(a) Production and trade patterns of substances in Table I and Table II

Detailed information on global production of all 23 chemicals under international control is not available. There is, however, some information on the geographical spread of the licit manufacture of precursor chemicals, suggesting that such production is a global phenomenon.

Twenty Governments officially reported production of substances in Table I during the 2010-2012 period. Combining this information with trade statistics (Governments reporting more exports than imports of Table I precursor chemicals during the 2010-2012 period) suggests that production of Table I precursors is probably taking place in 47 countries and areas. The manufacture of Table I and Table II precursors may occur in 77 countries and areas, representing about half of the 163 countries and areas for which information is available (see map 1).58 The com-

51 General Assembly resolution S-20/4 B, para. 14 (b).
53 Ibid., Plan of Action, paras. 35 and 39. While the 1988 Convention excluded pharmaceutical preparations from the control efforts (para. 14), the 2009 Plan of Action, as a consequence of the changed situation, stated in its paragraph 36 (c) that Member States should “strengthen controls, including through the Pre-Export Notification Online system, where required, for the import and export of preparations containing precursor chemicals, such as ephedrine and pseudoephedrine, which could be used in the manufacture of amphetamine-type stimulants”.
54 Ibid., paras. 41 (k) and (r).
55 Ibid., para. 39.
56 Ibid., para. 41 (s).
57 Ibid., para. 41 (u). That provision has not been widely used so far. While that could represent a major leap forward in strengthening and improving backtracking investigations, there are concerns about the costs involved and its actual value added. In addition, the “marking” involved in the provision could be potentially problematic if applied to chemicals used in the manufacture of pharmaceutical products, entailing expensive litigation if patients claim that such pharmaceuticals have been contaminated.
58 Twenty Governments reported licit manufacture of any of the 15 Table I precursor chemicals during the 2010-2012 period, out of a total of 104 Governments reporting to UNODC in part I of the annual reports questionnaire. According to UN COMTRADE, 73 countries exported Table I precursor chemicals during the 2010-2012 period, i.e. almost half of the countries contained in that database.
The combined population of the area concerned accounts for about 77 per cent of the world’s population.

The largest proportion of licit exports of the 23 internationally controlled chemical precursors during the 2010-2012 period were from countries in Asia (41 per cent of the total in value terms), followed by countries in Europe and the Americas (see table 1).

The largest proportion of such exports in Asia during that period were made by the Republic of Korea, followed by Japan, Singapore, Thailand, China and India. The largest exporter in Europe was Belgium, followed by Germany, the Netherlands and Spain. In the Americas, the list was topped by the United States, followed by Canada, Mexico and Brazil. The main exporter in Africa was South Africa, followed by Zambia, Nigeria, Egypt and Kenya. The largest exporter in the Oceania region was Australia, followed by New Zealand. The role of different countries in the licit trade of controlled precursors can be a function of multiple elements: the size of their chemical industry, the domestic demand for chemicals and the trade sector, which may also be influenced by the existence of large seaports. The correlation between exports and imports of precursor chemicals during the 2010-2012 period was weaker than for chemicals in general, suggesting that re-exports, though common, occurred less frequently for precursor chemicals than for chemicals in general.

If only the “net exports” of precursors are considered (i.e. the difference between precursor exports and precursor imports), which may be a better reflection of underlying production, data show an even stronger concentration of such “net exports” of precursors from countries in Asia (59 per cent of the total).

If the analysis is restricted to Table I precursor chemicals, the largest proportion of licit exports during the 2010-2012 period were reported, in descending order, by Belgium, China, Mexico, the United States, India, Germany, the Netherlands and Switzerland. Aggregated to the regional level, the largest proportion of exports and imports of substances listed in Table I were accounted for by Europe (44 per cent of exports and 65 per cent of imports), Asia (29 per cent and 18 per cent, respectively) and the Americas (27 per cent and 14 per cent, respectively). In terms of net exports, Asia accounts for 50 per cent of the global total (mainly China, followed by India) and the Americas for 38 per cent (mainly Mexico, followed by the United States).
States), while Europe accounts for “just” 12 per cent, reflecting the fact that a significant proportion of European precursor chemical exports are nowadays “re-exports” of imported substances.

(b) Economic importance of substances listed in Table I and Table II

Data from UN COMTRADE indicate that precursor chemicals account for a very small share of the overall market for chemicals. Total international trade in precursor chemicals amounted to approximately $9 billion in 2012, which is equivalent to just 0.5 per cent of total international trade in chemicals.

Although there were 15 substances listed in Table I and only 8 in Table II, the latter substances accounted for 93 per cent of the international trade in precursor chemicals, based on 2012 data (see table 2). The largest (licit) international trade amounts were reported for toluene (40 per cent of total exports in 2012), a chemical used as a solvent (paint thinner) and as an octane booster in gasoline fuels, although it is also used in the processing of cocaine. The second-largest amounts were reported for acetone (22 per cent), a widely used solvent and a chemical used in cocaine and heroin processing, followed by sulphuric acid (14 per cent), a chemical used in the manufacture of cocaine, and amphetamine-sulphate, which in the licit market is required, inter alia, in the production of fertilizers, detergents, pharmaceuticals, insecticides, anti-freezes, explosives, textiles and lubricants.

The economic importance of international trade in substances listed in Table I is far lower. Table I precursors, which are under tighter control, account for only 7 per cent of international trade in precursors. Expressed as a proportion of total exports, substances in Table I comprise a mere 0.04 per cent of all chemicals traded at the global level. The most important substance in Table I is acetic anhydride, which is employed, inter alia, in the manufacture of heroin. It accounts for global international licit trade of some $0.4 billion, or about 4 per cent of global exports in precursor chemicals. The next most important Table I precursors are potassium permanganate, involved in the manufacture of cocaine (exports of $70 million, or 0.8 per cent of global exports of precursor chemicals) and pseudoephedrine ($63 million, or 0.7 per cent), which is used in the manufacture of methamphetamine, followed by piperonal ($44 million, or 0.5 per cent) part of the manufacture of 3,4-methylenedioxy-N-methylamphetamine (MDMA), commonly known as “ecstasy”.

(c) Trends in the licit trade of Table I and Table II precursors

Expressed in constant United States dollars, global exports of precursor chemicals rose almost fivefold during the 1996-2012 period. Even accounting for inflation, such exports still rose threefold over this period.

There was, however, a marked difference between Table I and Table II precursors.
and Table II precursors. While Table II precursor chemicals rose three-and-a-half times in constant dollars over the 1996-2012 period, the increase in the more strictly controlled substances in Table I amounted to 35 per cent (see figure 12).

2. Trafficking in Table I and Table II substances

One way to examine trafficking in precursor chemicals is to analyse statistics relating to seizures, although these may reflect variations in law enforcement efforts and changes in trafficking patterns. Information on seizures also provides only a partial picture of trafficking of precursors because law enforcement activities in this area are geared towards the prevention of diversion (e.g. via stopped suspicious shipments) and the detection of clandestine laboratories.

Fig. 12. Global exports of precursor chemicals in constant 2012 dollars, 1996-2012

Source: Data from UN COMTRADE (based on HS96 classification).
Compared with seizures of all drugs, seizures of precursors are concentrated in a smaller number of countries and are the result of fewer operations. They are often the result of joint international operations and are characterized by the interception of large volumes per seizure case. A relatively low, though rising, number of Governments report such seizures. The number increased from 37 in 2002 to 61 in 2012, reflecting improvements in precursor control as well as a greater geographical spread in the smuggling of precursors. The number of Governments reporting seizures of precursors is still, however, only half of the number reporting drug seizures (124 in 2012). Over the 2002-2012 period, 96 Governments reported seizures of precursors, compared with 146 reporting seizures of drugs.

Owing to the smaller number of seizures involved, seizures of precursors are characterized by large annual fluctuations, which makes trend analyses difficult to interpret and often rather speculative.

The annual fluctuations have been very large for seizures of Table I precursors, which peaked in 2011, primarily reflecting a massive rise of seizures of the amphetamine-type stimulants precursor phenylacetic acid and its derivatives and some increases in acetic anhydride, potassium permanganate, ephedrine and safrole.

Preliminary figures for 2012, in contrast, show some of the lowest seizure figures for substances in Table I in the past two decades (see figure 13). Declines were reported primarily for phenylacetic acid and acetic anhydride. Some of the decline also reflects the fact that seizure information is not yet available from all countries, i.e. totals may still rise. Seizures of potassium permanganate, several of the precursors of amphetamine-type stimulants and the precursors of lysergic acid diethylamide (ergotamine, lysergic acids) rose in 2012.

Seizures of substances in Table II show a different pattern. Overall seizures of such substances peaked in 2002 and in 2004 (see figure 14). The 2002 peak was mainly the result of acetone seizures, while the 2004 peak was linked to seizures of hydrochloric acid. Since then, overall seizures have been at far lower levels. The underlying trend, except for the two peaks, appears to have been stable. This is in contrast to international licit trade in these substances, which has greatly increased over the past two decades. In recent years, seizures of substances in Table II have been dominated mainly by seizures of sulphuric acid and/or acetone. During the 1990-2012 period, seizures of substances in Table II accounted in volume terms for almost 98 per cent of all seizures of chemicals controlled under the 1988 Convention.

The regional distribution of seizures of substances in Table I and Table II shows a concentration in the Americas, followed, depending on the time frame used, by either Europe or Asia. The largest overall precursor seizures in volume terms during the 2002-2012 period were reported by countries in North America (59 per cent of the total), followed by South America (12 per cent), Europe (4 per cent) and...
Asia (3 per cent). Africa accounted for 0.05 per cent and the Oceania region for 0.02 per cent.

If the analysis is restricted to more recent years (2007-2012), the largest seizures were made in South America (60 per cent of the total), followed by North America (17 per cent), Asia (15 per cent, of which the bulk (13 per cent of the world total) were made in East and South-East Asia) and Europe (8 per cent). Seizures in the Oceania region accounted for 0.1 per cent and Africa for 0.04 per cent of the total.

F. KEY PRECURSORS USED IN THE ILLICIT MANUFACTURE OF DRUGS

1. Key chemical used in the manufacture of cocaine: potassium permanganate

(a) Use

Potassium permanganate has a broad range of licit applications, mostly derived from its characteristic as an oxidizing agent in chemical reactions. Those applications include use as a disinfectant for hands; for the treatment of dermatitis, fungal infections and mouth ulcers; for fruit preservation and disinfection of vegetables; treatment of drinking water and wastewater; and as an oxidant and reagent for the synthesis of various organic compounds. Significant amounts are required for the synthesis of ascorbic acid (used for vitamin C tablets) and saccharin (an artificial sweetener). Solutions of potassium permanganate with hydrogen peroxide were used to propel rockets and are still used to propel torpedoes.

Potassium permanganate is also used in the illicit manufacture of cocaine. It is employed in the processing of coca paste into cocaine base, and is critical for achieving a proper crystallization of cocaine HCl later in the process, and ultimately for obtaining high-quality cocaine.

(b) International trade

Global exports of potassium permanganate (based on data from UN COMTRADE) amounted to 25,400 tons in 2012, exceeding globally reported imports (17,500 tons). This indicates discrepancies in the reporting of trade statistics, along with possible underreporting of imports.

The value of global exports of potassium permanganate amounted to slightly more than $70 million in 2012 (equivalent to 0.004 per cent of global chemical exports in 2012), up from $23 million in 1996 (see figure 15).

During the 2007-2012 period, a total of 66 Governments reported exports of potassium permanganate, while 141 Governments reported imports. Total exports amounted to $55.3 million per year during the period. The largest exporters were China (54 per cent of the total), followed by the United States (14 per cent), Belgium (11 per cent) and India (7 per cent).

The largest importer of the substance in South America during that period was Brazil, with imports of about 1,000 tons per year, more than 90 per cent of which originated in China. Annual licit imports into the three main cocaine-producing countries were far lower: 45 tons for Peru, 29 tons for Colombia and 6 tons for the Plurinational State of Bolivia. The potassium permanganate required

67 If correctly reported, total imports and exports at the global level should be equal in weight terms.
tons per year) for the manufacture of illegal cocaine is rather large compared with an annual total of 1,500 tons of legal imports into South America, Central America and the Caribbean during the 2007-2012 period, suggesting that diversion from the licit market happens before it reaches the region and/or that it is being produced domestically in clandestine laboratories in the Andean region.

(c) Trafficking

Following initially high seizures of potassium permanganate in 1989, when the substance was placed under international control, seizures remained rather modest during the following decade before rising sharply in 1999 in the wake of Operation Purple (launched under the auspices of the International Narcotics Control Board in April 1999), which focused on the tracking of potassium permanganate and led to a temporary shortage of the chemical in the Andean region. As a consequence, alternative substances were used and operators of cocaine laboratories (notably in Colombia) experimented with the illegal production of potassium permanganate in clandestine laboratories. Further noteworthy seizures were made during the 2004-2007 period as part of Operation Cohesion. Seizures subsequently declined, in parallel with declines in global cocaine production and falling purity levels in North America, until 2009 and remained at lower levels before climbing again in 2012 (see figure 16).

Thirty-nine Governments reported seizures of potassium permanganate during the 2002-2012 period, including 31 Governments during the 2007-2012 period. Global average annual seizures of the substance totalled 65 tons during the 2007-2012 period, equivalent to 0.3 per cent of global licit exports.

South America accounted for 88 per cent of seizures, reflecting the use of the substance in the illegal manufacture of cocaine in the Andean region, followed by Asia (9 per cent), mostly China (8 per cent of total global seizures). The bulk of the seizures made by China took place in 2012, reflecting improved control measures in that country. The International Narcotics Control Board reported that more than three quarters of all pre-export notifications for potassium permanganate in 2011 were issued by China, followed by the United States and India.

The largest seizures worldwide were reported by Colombia (80 per cent during the 2007-2012 period), followed, in the Americas, by the Plurinational State of Bolivia (4 per cent) and Peru (2 per cent). Average annual seizures fell by half in Colombia during the 2007-2012 period as compared with the 2002-2006 period, but more than tripled in Peru and rose 27-fold in the Plurinational State of Bolivia. Those patterns reflect a decline in cocaine production in Colombia, as well as the growing importance of both the Plurinational State of Bolivia and Peru as not only coca-producing countries but also cocaine-manufacturing countries.

68 See calculations in subsection 1 (a) of section G below.
There are indications that significant amounts of potassium permanganate are produced illegally in the Andean region. In 2011, Colombian authorities dismantled seven laboratories producing the substance; in 2012, eight such laboratories were dismantled.\textsuperscript{74} The International Narcotics Control Board cites estimates that between 60 and 80 per cent of the potassium permanganate used in Colombia is obtained nowadays through illicit manufacture of the substance using manganese dioxide as a starting material.\textsuperscript{75} Backtracking investigations also suggest that potassium permanganate has been diverted from domestic distribution channels abroad and then smuggled into the Andean region and/or that alternative chemicals have been used.\textsuperscript{76}

Smaller amounts were also seized in Argentina, Brazil, Chile, Ecuador and Venezuela (Bolivarian Republic of), i.e. in countries neighbouring the three main cocaine-producing countries, during the 2007-2012 period. In 2013, small amounts were also found in dismantled cocaine-processing laboratories in the Dominican Republic and Panama.\textsuperscript{77}

2. Key chemical used in the manufacture of heroin: acetic anhydride

(a) Use

Acetic anhydride is used mainly as an acetylating and dehydrating agent in the chemical and pharmaceutical industries. It is a versatile reagent and is used, inter alia, in the production of aspirin and the conversion of cellulose to cellulose acetate, a substance used for photographic films, adhesives, synthetic fibres and as a frame material for eyeglasses. It is also used as a wood preservative, for polishing metals and in the production of brake fluid, dyes and explosives.

In addition, acetic anhydride is used in the manufacture of heroin and, to a lesser extent, in the manufacture of other drugs, such as methaqualone, or in the conversion of phenylacetic acid to P-2-P. The synthesis of heroin, also known as “diacetylmorphine”, is a simple one-step acetylation reaction of morphine using acetic anhydride.\textsuperscript{78}

(b) International trade

Estimates of annual licit production of acetic anhydride range from 1.1 million tons (2011)\textsuperscript{79} to 2.13 billion litres, or 2.3 million tons,\textsuperscript{80} per year. The latest estimate of the International Narcotics Control Board is close to 1.5 million tons per year.\textsuperscript{81}

Global exports of acetic anhydride in 2012 reached 397,000 tons, while global imports reached 414,000 tons, suggesting that international trade amounts to some 28 per cent of global production of the substance. Global licit exports of acetic anhydride rose, in real terms, by 80 per cent during the 1996-2012 period (see figure 17). This was less than the rise in chemical exports in general.

During the 2007-2012 period, 118 Governments reported importing acetic anhydride, while 45 reported exports of the substance. The largest exporters in Asia were China and Japan; in North America, the United States and Mexico; and in Europe, Belgium and the Netherlands. In terms of “net exports”, North America predominates (Mexico followed by the United States).

Officially reported licit imports into South-West Asia, however, were very small. There were no licit imports into Afghanistan. Licit imports into Pakistan fell from 149 kg

in 2007 to 5,299 units in 2011. Similarly, the number of dismantled coca paste and base laboratories in Peru rose from 649 in 2007 to 1,498 in 2011 while the number of cocaine crystallization laboratories there rose from 16 in 2007 to 21 in 2010 and still 19 in 2011. In contrast, the number of coca paste/base laboratories in Colombia declined from 3,147 in 2008 to 2,200 in 2011 while the number of dismantled cocaine crystallization laboratories fell in Colombia from 296 to 200 over the same period. (UNODC, Colombia, Monitoreo de Cultivos de Coca 2011 and previous years; Peru, Monitoreo de Cultivos de Coca 2011 and previous years; and Estado Plurinacional de Bolivia, Monitoreo de Cultivos de Coca 2011 and previous years.)

\textsuperscript{74} Data from the annual reports questionnaire of UNODC.
\textsuperscript{80} International Narcotics Control Board, \textit{Precursors Report}, 2012, box 1. One kilogram of acetic anhydride is equivalent to 0.926 litres of acetic anhydride.
in 2008 to 14 kg in 2012, according to data from UN COMTRADE. That is far below the requirements of Afghanistan’s opiate industry. No licit acetic anhydride imports were reported by the Islamic Republic of Iran or any of the other countries bordering Afghanistan (except China). Yet, clandestine heroin production and seizures of acetic anhydride in West Asia, notably in Afghanistan, were substantial. This suggests that most of the acetic anhydride destined for the subregion originates as diversions made outside the subregion.82

In Asia, relatively large imports of acetic anhydride during the 2007-2012 period were reported by China (24,400 tons per year), the Republic of Korea (10,600 tons), Singapore (6,700 tons), Thailand (4,000 tons) and India (1,200 tons). Historically, the largest importer in South-Eastern Europe has been Turkey (1,400 tons per year), an important trans-shipment location for acetic anhydride diverted in Europe and smuggled into Afghanistan. During the same period in Asia, relatively large exports were reported by Saudi Arabia (17,100 tons per year), the United Arab Emirates (15,800 tons),83 China (11,400 tons), Japan (8,200 tons), Singapore (5,700 tons) and India (2,300 tons).

(c) Trafficking

Following increases in seizures of acetic anhydride in the 1990s, and a peak reached in 2001 in the wake of the implementation of Operation Topaz (which started in late 2000), seizures fell in the first few years of the new millennium, possibly as a delayed reaction to the 2001 Afghan opium poppy ban, before recovering as precursor control gained a new impetus in the wake of the introduction of Operation Cohesion in 2006. Even though seizures declined in 2012, the underlying trend seems to be upwards (see figure 18).

Seizures of acetic anhydride were reported by 43 Governments during the 2002-2012 period. Global annual seizures during the 2007-2012 period amounted to approximately 131,000 litres, equivalent to just 0.03 per cent of global imports.

The largest seizures were made in “West Asia”84 (34 per cent of the world total), mostly reflecting seizures made in Afghanistan (22 per cent of the world total).

Afghanistan has no legitimate trade in or manufacture of acetic anhydride. Despite that fact, sizeable quantities of the substance are diverted each year from domestic trade in other countries before being smuggled into Afghanistan.85

Countries close to Afghanistan are at a particular risk of being targeted to obtain and traffic acetic anhydride into Afghanistan. “That applies particularly to China, India, Islamic Republic of Iran and Uzbekistan – countries that manufacture acetic anhydride or countries in which a significant amount of the substance is available because of domestic or international trade” 86 as well as to Iraq 87. Two recent large seizures made in Pakistan88 and the Islamic Republic of Iran89 show how these countries continue to be used as transit countries for such shipments.

The next largest seizures were reported by countries in Europe90 (27 per cent of the total during the 2007-2012 period). The largest, in order of size, were made in Slovenia, Hungary, the Russian Federation, Bulgaria and Slovakia.

During the 2002-2012 period, Turkey reported regular seizures of acetic anhydride, typically originating in Western and Central Europe.91 Overall seizures of acetic anhydride in Turkey have shown a downward trend, possibly reflecting the declining importance of Europe as a source region.

83 This reflects huge exports of 94,749 tons of acetic anhydride in 2008, while no exports were reported in other years.
84 According to Board classification, West Asia includes countries in the Near and Middle East, Central Asia, Turkey and the Caucasus.
87 In January 2012, Iraqi authorities objected to a shipment of 32 tons of acetic anhydride from China. (INCB, 2012 Precursors and chemicals frequently used in the illicit manufacture of narcotic drugs and psychotropic substances, New York 2013, p. 25).
88 In mid-2013, for instance, 15 tons of acetic anhydride were seized while transiting Pakistan on its way to Afghanistan (International Narcotics Control Board, Precursors Report, 2013, para. 111).
89 A recent example was a shipment of 17.8 tons of acetic anhydride from China via the Islamic Republic of Iran to Afghanistan, which was seized by the Iranian authorities in June 2013. (International Narcotics Control Board, Precursors Report, 2013, para. 111).
90 According to the International Narcotics Control Board classification, which excludes Turkey.
91 One of the largest cases involved the seizure of 17 tons of acetic anhydride in Turkey in December 2010 on a truck which had loaded the chemicals in Slovakia and was, officially, said to be transporting disinfectants.
Seizures in North America, which accounted for 26 per cent of the world total during the 2007-2012 period, were made mainly by Mexico (15 per cent of the world total) and the United States (11 per cent). Such seizures were increasingly linked to the illicit manufacture of methamphetamine, and increased after 2009.

Seizures in East and South-East Asia accounted for 11 per cent of the world total during the 2007-2012 period, primarily reflecting seizures made in China (8 per cent of the world total), followed by the Republic of Korea and Japan. The only other country in South-East Asia reporting annual seizures during the 2002-2010 period was Myanmar, the world’s second-largest producer of opium.

As reported by the Interntional Narcotics Control Board, “while seizures are an important indicator of the level of activity of drug trafficking organizations, it is important to note that they are also indicators of known diversions that have been successful. The international precursor control system is primarily aimed at the prevention of diversion. Comparative figures on stopped, suspended or suspicious shipments show that although seizures of acetic anhydride during the period 2008-2011 amounted to 551,000 litres, nearly double that amount — 943,000 litres — was either stopped or suspended (a total of 761,000 litres) or identified as suspicious (182,000 litres) through the PEN Online system.”

### 3. Key methamphetamine precursors: ephedrine and pseudoephedrine

(a) Use

Ephedrine and/or pseudoephedrine have been the key precursors used in the manufacture of methamphetamine for many years. In addition, they are used in the illegal manufacture of methcathinone, another amphetamine-type stimulant.

Ephedra, known as má huáng in traditional Chinese medicine, contains both ephedrine and pseudoephedrine. Its use has been documented since the Han Dynasty (206 B.C.-220 A.D.), in the treatment of asthma and bronchitis and as a stimulant. Licit uses of ephedrine as a pharmaceutical product include cough medicine (bronchodilators), while pseudoephedrine is often used in nasal decongestants. In combination with promethazine, ephedrine is used to combat seasickness. Ephedrine is also found on the WHO list of essential medicines “for use in spinal anaesthesia during delivery, to prevent hypotension”. In addition, ephedrine preparations are sold as food supplements or pills to lose weight and reduce body fat.

A total of 113 Governments reported licit requirements for ephedrine to the Board, and 108 reported requirements for pseudoephedrine (out of a total of 153 Governments reporting). The bulk of the requirements for these substances concerned pseudoephedrine (see figure 19). The largest licit demand for those substances was in Asia (60 per cent of the total), followed by the Americas (18 per cent), Europe (13 per cent), Africa (8 per cent) and the Oceania region (0.4 per cent). The single largest markets for ephedrine and pseudoephedrine in volume terms were India (18 per cent of the world total) and China (17 per cent), followed by the United States (13 per cent), the United Kingdom (4.2 per cent), the Republic of Korea (3.9 per cent), Switzerland (3.3 per cent), Pakistan (3.2 per cent), Egypt (3.1 per cent), Singapore (2.9 per cent), Indonesia (2.7 per cent), the Islamic Republic of Iran (2.5 per cent), the Syrian Arab Republic (2.3 per cent) and Nigeria (1.5 per cent).

Note: Based on information from 153 Governments.

18th list (April 2013).

94 World Health Organization, *WHO Model List of Essential Medicines:*

94 World Health Organization, *WHO Model List of Essential Medicines:*

95 “Annual legitimate requirements for ephedrine and pseudoephedrine include quantities of those substances that may be manufactured domestically and/or imported into the country to provide adequate supplies of each chemical for estimated medical, scientific, research and industrial needs; licit export requirements; and establishment and maintenance of reserve stocks.” (International Narcotics Control Board, “Issues that Governments may consider when determining annual legitimate requirements for ephedrine and pseudoephedrine”. Available from www.incb.org/incb/en/precursors/precursors/tools_and_kits.html.)

97 Ibid.
Global international trade in ephedrine and pseudoephedrine declined during the 1996-2012 period (see figure 20).

Global exports of ephedrine amounted to, on average, 133 tons per year during the 2007-2012 period, or roughly half of reported imports (264 tons per year). That discrepancy once again indicates problems with regard to reporting of trade statistics.

Thirty Governments reported exports of ephedrine, while 92 reported imports, during the 2007-2012 period. The largest ephedrine exports were reported by India (59 per cent). The largest imports were reported by the United States (20 per cent) and Egypt (19 per cent), followed by the Republic of Korea (8 per cent) and Nigeria (6 per cent).

Global pseudoephedrine exports amounted to, on average, 1,136 tons per year during the 2007-2012 period, exceeding imports (863 tons per year). Thirty-five Governments reported exports of pseudoephedrine, while 96 Governments reported imports during that period. The largest exports were reported by India (52 per cent of the total), followed by Germany and China. According to the United States Department of State, Taiwan Province of China was actually the third-largest exporter worldwide of pseudoephedrine during the 2009-2011 period. The largest pseudoephedrine imports during the 2007-2012 period were recorded by the United States (25 per cent), followed by Egypt (8 per cent).

While there has been a marked upward trend in overall seizures of precursors used in the manufacture of methamphetamine and amphetamine (see figure 21), that has not been the case with regard to the “traditional” methamphetamine precursors, ephedrine and pseudoephedrine.

Global seizures of ephedrine and pseudoephedrine peaked in the second half of the 1990s and again in 2004 before falling in subsequent years (see figure 22). The initial increases were in line with reports of strong growth in the clandestine manufacture of methamphetamine since the mid-1990s. The declines in recent years seem to reflect improved controls for these substances, along with the emergence of alternative precursor chemicals such as phenylacetic acid and a number of chemicals not under international control. In addition, data show that the use of pharmaceutical preparations containing ephedrine or pseudoephedrine has increased in recent years.99

Seizures of ephedrine were reported by 54 Governments and seizures of pseudoephedrine by 50 Governments during the 2002-2012 period. Total seizures of both substances amounted to, on average, 56 tons per year during the 2007-2012 period, equivalent to 21 per cent100 of global licit imports (based on UN COMTRADE data), a very high proportion as compared to potassium permanganate or acetic anhydride, which both had ratios of clearly less than 1 per cent.

The bulk of the seizures were made by countries in North America (43 per cent) and East and South-East Asia (22 per cent), reflecting the concentration of global methamphetamine production in those two regions, followed by Central America (14 per cent), an emerging transit region. The largest seizures by individual countries during the 2007-2012 period were reported by the United States (32 per cent of the total), followed by China (18 per cent) and Mexico (11 per cent).

East and South Asia continue to be the origins of pseudoephedrine and ephedrine used in illicit manufacture of methamphetamine in the region and in Oceania.101 Seizures of ephedrine and pseudoephedrine in Mexico have been declining strongly following improved controls in the country in 2009, which prompted clandestine operators of methamphetamine to shift to alternative precursors.

While Mexico is a major supplier of methamphetamine, the country does not seem to have clandestine facilities or

99 International Narcotics Control Board, Precursors Report, 2013 (and previous years).

100 Based on international trade data collected by the International Narcotics Control Board, the proportions during the 2007-2011 period amounted to 14 per cent for bulk ephedrine and 2 per cent for pseudoephedrine (Precursors report, 2012, table 1).

101 UNODC, Patterns and Trends of Amphetamine-Type Stimulants and Other Drugs: Challenges for Asia and the Pacific, Global SMART Programme 2013.
F. Key precursors used in the illicit manufacture of drugs

WORLD DRUG REPORT 2014

75

chemical plants that synthesize or manufacture pseudoephedrine or ephedrine powder. Mexico dismantled 259 methamphetamine laboratories in 2012, up from a few dozen a few years earlier, and it reported the world’s largest aggregated amount of seizures of methamphetamine for the period 2010-2012.

Most of the seizures of these precursors in East and South-East Asia involved ephedrine (80 per cent). There was also a significant domestic demand for both ephedrine and pseudoephedrine. China alone dismantled 228 clandestine laboratories producing methamphetamine in 2012.¹⁰² Significant seizures of ephedrine were also reported by Myanmar, another key producer of methamphetamine in the region, followed by the Lao People’s Democratic Republic; Malaysia; the Philippines; Thailand; Indonesia; Japan; Macao, China; Hong Kong, China; Cambodia; and the Republic of Korea. Traditionally, most of the shipments of ephedrine and pseudoephedrine to countries and areas in the region originate within the subregion or in South Asia.

4. Key amphetamine precursors: P-2-P and phenylacetic acid

(a) Use

One of the key precursors for the manufacture of amphetamine (and in recent years also of methamphetamine) is phenyl-2-propanone (P-2-P), or phenylacetone, also known as benzyl methyl ketone (BMK). This substance is mainly used for the manufacture of amphetamine and some

of its derivatives, as well as for the synthesis of another stimulant drug, propylhexedrine. The latter substance is frequently sold over-the-counter as an inhalant (e.g. Benzedrex) to provide temporary relief of nasal congestion, and as an appetite suppressant (e.g. Obesin).

Global licit requirements for P-2-P reported to the Board amount to some 65 tons per year, a modest amount compared with the reported requirements for ephedrine (close to 400 tons) or pseudoephedrine (more than 1,700 tons). The bulk of the reported licit requirements for P-2-P was from countries in North America (96 per cent of the total), followed by Europe (4 per cent). Small requirements were also reported by Governments in Oceania, Asia, South America and the Caribbean.\(^{103}\)

One of the potential precursors for P-2-P is phenylacetic acid, which itself is employed to treat type II hyperammonemia, a metabolic disturbance characterized by an excess of ammonia in the blood that can lead to encephalopathy (a brain disorder). Moreover, phenylacetic acid is used in the production of penicillin G (benzylpenicillin), as well as in the treatment of syphilis, diphtheria, meningitis, gonorrhoea, aspiration pneumonia and septic arthritis. Phenylacetic acid is also used in some perfumes.

(b) International trade

Average global exports of P-2-P during the 2007-2012 period amounted to 77 tons, while average annual imports amounted to 143 tons, once again indicating significant reporting discrepancies. Fifteen Governments reported exports of P-2-P during the 2007-2012 period. The largest exporters were France (51 per cent), followed by India (14 per cent) and Egypt (14 per cent).

The number of Governments reporting imports of P-2-P during the 2007-2012 period amounted to 52. The largest importers were the United States (53 per cent), followed by China (17 per cent), Jordan (6 per cent), Poland (5 per cent) and Egypt (4 per cent). In 2012, the largest importers was the United States, followed by Pakistan.

International trade in phenylacetic acid is substantially larger. Total exports amounted to 4,800 tons per year and total imports to 5,900 tons per year during the 2007-2012 period. The largest exporter during the 2007-2012 period was China (75 per cent), followed by the United States (16 per cent) and India (7 per cent). The largest importer was Mexico (32 per cent). A total of 32 Governments reported exports of phenylacetic acid, while 79 reported imports of phenylacetic acid during the 2007-2012 period.

Combined global exports of P-2-P and phenylacetic acid in 2012 remained at similar levels as in 1996 (see figure 23). A decline of 59 per cent in exports of phenylacetic acid during the 2007-2012 period was linked mostly to lower exports by the United States, China and India, while lower imports were reported mainly from Mexico, the United Kingdom and Spain. Declines in 2012 can be ascribed to falling exports from China; declines in imports were mainly the result of improved controls in Mexico.

(c) Trafficking

The overall trend with regard to total combined seizures of P-2-P and phenylacetic acid appears to have been upwards (see figure 24). The rise in seizures until 2011 was primarily a result of seizures of phenylacetic acid, which is increasingly being used in North American methamphetamine production. The peak in 2011 may in part have been a result of the transfer of phenylacetic acid from Table II to Table I of the 1988 Convention in that year and thus of stricter monitoring and controls. Moreover, the international Operation Phenylacetic Acid and its Derivatives, conducted under Project Prism in 2011 by the Board, appears to have played an important role.

Average annual seizures of P-2-P during the 2007-2012 period amounted to 8.3 tons, while average annual seizures of phenylacetic acid reached 216.7 tons. Seizures of the latter were higher than those of ephedrine and pseudoephedrine. Global seizures of P-2-P were equivalent to 6 per cent of global P-2-P imports, and phenylacetic acid seizures were equivalent to 4 per cent of global phenylacetic acid imports during the 2007-2012 period.\(^{104}\) These were smaller proportions than for ephedrine and pseudoephedrine (based on UN COMTRADE data).

Seizures of P-2-P were reported by 22 Governments and seizures of phenylacetic acid by 20 Governments during

\(^{103}\) In total, 24 countries reported licit requirements for P-2-P to the Board. (International Narcotics Control Board, Precursors Report, 2013, annex II.)

\(^{104}\) Based on international trade statistics collected by the Board, seizures of P-2-P were equivalent to 15 per cent of international trade, and phenylacetic acid equivalent to 11 per cent of international trade during the 2007-2011 period. (International Narcotics Control Board, Precursors Report, 2012, table 1.)
the 2002-2012 period, fewer than the number reporting seizures of ephedrine or pseudoephedrine.

During the 2002-2012 period, 38 per cent of global P-2-P seizures were made in Europe, which is the main amphetamine production centre, followed by East and South-East Asia (32 per cent) and North America (30 per cent). During the 2007-2012 period, most seizures were made in North America (50 per cent), where P-2-P has been used in the manufacture of methamphetamine. The largest seizures were reported by Mexico (38 per cent of the total), followed by the Netherlands and Canada (12 per cent each) and Belgium and China (10 per cent each).

In the case of phenylacetic acid, North America accounted for 98 per cent of total global seizures during the 2007-2012 period. Forensic profiling of seized methamphetamine in the United States confirmed that nearly all methamphetamine is now being manufactured using phenylacetic acid or other P-2-P-based methods (94 per cent of all samples tested in the second quarter of 2012, up from 69 per cent in 2010 and close to 0 per cent in 2007).105

5. Key “ecstasy” precursors: 3,4-MDP-2-P, safrole, isosafrole and piperonal

(a) Use

The “traditional” precursor for the manufacture of MDMA (“ecstasy”) is 3,4-methylenedioxyphenyl-2-propanone (3,4-MDP-2-P), also known as PMK (piperonyl methyl ketone) or in international trade statistics as 1-(1,3-benzodioxol-5-yl)propan-2-one.106 Its licit use is limited.

Safrole, a precursor of 3,4-MDP-2-P and MDMA (“ecstasy”), is produced mainly from the sassafras plants. According to a study in South-East Asia, the plant is found largely in China, Myanmar and Cambodia. Other studies reveal that it can also be produced from a number of plants grown in other parts of the world, notably in the Americas.108 In East and South-East Asia, more than 360 plants containing essential oils rich in safrole were identified. The most widely used plants are those of the Cinnamomum genus. Sassafras oil is used mainly in the manufacture of safrole, which is used in the manufacture of pesticides, insecticides and some fragrances. Safrole is also used for its antiseptic properties and as a pediculicide to treat lice. In addition, it serves as an additive in products such as root beer, sassafras tea or pinga com sassafras (Brazil).

Given indications of its carcinogenic properties, however, safrole has been banned as a food additive in a number of countries, including the United States and several European Union countries.110 Similarly, for health reasons, the International Fragrance Association issued a recommendation in 1987 to prohibit or limit its use in fragrance ingredients.

Isosafrole, another precursor of 3,4-MDP-2-P, is an isomer of safrole. Although it can be produced synthetically out of safrole, it is also derived from sassafras oil. It is used in the fragrance industry. Isosafrole is used for making soaps

106 That terminology may have led to some misunderstandings, however, and thus resulted in erroneous classifications.

107 “Safrole-rich essential oils — risk of illicit use”, in Eastern Horizons (UNODC Regional Centre for East Asia and the Pacific, Summer-Autumn 2007), pp. 9-10.

and perfumes, as well as in the manufacture of preservatives as an antiseptic agent. It is also a key precursor for the manufacture of piperonal.

Piperonal, a further precursor for 3,4-MDP-2-P and 3,4-methylenedioxyamphetamine (MDA), is another organic compound commonly found in fragrances and flavours. Piperonal occurs in a range of plants, including dill, violets, black pepper and vanilla, but it is also produced by oxidation of isosafrole. Piperonal itself is sometimes used in aromatherapy.

(b) International trade

In terms of legal trade, piperonal is nowadays by far the most important substance among the “ecstasy” precursor chemicals. Global piperonal exports increased during the 1996-2012 period, while exports of the other chemicals declined after reaching a peak in 1998. The strong decline in exports of “ecstasy” precursors between 1998 and 2000 was the result mainly of a fall in isosafrole exports, reflecting improvements in precursor control owing to a significant upward trend in “ecstasy” use in key markets in the 1990s (see figure 25).

A total of 38 Governments reported exports of “ecstasy” precursor chemicals during the 2007-2012 period, amounting to, on average, $42 million per year. Imports were reported by 102 Governments ($45 million per year). The largest exporters of “ecstasy” precursor chemicals were China (56 per cent) and Hong Kong, China (21 per cent). The largest importers were Hong Kong, China (18 per cent) and the United States (17 per cent), followed by Germany (9 per cent), Spain (7 per cent), Switzerland (7 per cent) and the United Kingdom (5 per cent). China was the largest net exporter during the 2007-2012 period.

The totals primarily reflect international trade in piperonal of about $41 million per year. Exports of the substance were reported by 26 Governments; imports were reported by 84 Governments.

The second most widely traded substance was isosafrole: 18 Governments reported exports and 53 reported imports. They recorded annual exports of about $1 million and imports of $2.8 million per year during the 2007-2012 period, again indicating some significant reporting gaps.

Exports of 3,4-MDP-2-P amounted to about $0.3 million annually, while imports totalled $1.5 million per year during the 2007-2012 period, again indicating inconsistencies in reporting. There were a total of 15 Governments that reported exports and 46 that reported imports.

For safrole, 15 Governments reported exports and 45 reported imports. They recorded total exports of $0.09 million and imports of $0.17 million per year.

In both value and volume terms, piperonal is the most widely traded substance among MDMA precursors, according to UN COMTRADE data. Average annual exports during the 2007-2012 period amounted to 1,759 tons of piperonal, 62 tons of 3,4-MDP-2-P, 25 tons of isosafrole and 9 tons of safrole. If all of these exports are transformed into 3,4-MDP-2-P equivalents (based on the conversion ratios of the International Narcotics Control Board), the aggregated figure amounts to some 1,000 tons per year. The bulk of these exports in volume terms is accounted for by piperonal (91 per cent), followed by 3,4-MDP-2-P (6 per cent), isosafrole (2 per cent) and safrole (1 per cent). Calculations on the import side reveal a similar pattern.

Expressed in common 3,4-MDP-2-P equivalents, Board statistics suggest that about two thirds of international trade in “ecstasy” precursors relates to piperonal, and almost a third to safrole and oils rich in safrole. The other substances, isosafrole and 3,4-MDP-2-P, account for less than 1 per cent of the total (see figure 26).

Based on such figures, the overall international trade in (potential) “ecstasy” precursors would have amounted to, on average, 6,580 tons in 3,4-MDP-2-P equivalents during the 2007-2011 period. This is a significant discrepancy as it is more than six times the figure found in UN COMTRADE. The differences, of course, raise ques-

111 For more information, see http://micro.magnet.fsu.edu/primer/techniques/polarized/gallery/pages/heliotropinsmall.html.

112 Average annual imports of 1,726 tons of piperonal, 71 tons of isosafrole, 40 tons of 3,4-MDP-2-P and 18 tons of safrole during the 2007-2011 period. This would amount to approximately 1,000 tons in 3,4-MDP-2-P equivalents.

113 The comparison made exaggerates the actual difference, as sassafras oil is not specifically reported in UN COMTRADE statistics. Nevertheless, excluding sassafras oil, the overall total based on International Narcotics Control Board statistics would have still been almost five times larger than shown in the UN COMTRADE statistics. This is mainly owing to differences in the reported trade in piperonal, which...
tions as to the underlying reasons for this apparent over-reporting or underreporting by Member States in the case of “ecstasy” precursors.

(c) Trafficking

In line with global seizures of “ecstasy”, the overall trend with regard to the seizure of “ecstasy” precursors was upwards in the 1990s, peaking in 2000 and again in 2007 before falling sharply during the 2007-2010 period and remaining, despite some recovery, at lower levels until 2012 (see figure 27). Overall seizures of “ecstasy” precursors amounted to some 16 tons per year during the 2002-2012 period and were thus far lower than seizures of amphetamine precursors (209 tons per year during the same period).

If total seizures during the 2002-2012 period are considered, most seizures of “ecstasy” precursors were for safrole (44 per cent), followed by 3,4-MDP-2-P (33 per cent), piperonal (23 per cent) and isosafrole (0.2 per cent). There have been frequent changes in the type of “ecstasy” precursors used, however. In most years during the 1996-2006 period, the “traditional” “ecstasy” precursor, 3,4-MDP-2-P, was the most widely seized substance. During the 2007-2012 period, improved controls of 3,4-MDP-2-P prompted organized criminal groups to look for alternatives, which led to the use of safrole and various safrole-containing oils. For the same period, about 85 per cent of all seizures of “ecstasy” precursors turned out to be related to safrole, 8 per cent to piperonal and only 7 per cent to 3,4-MDP-2-P: Less than 1 per cent were related to isosafrole. All of this is in sharp contrast to licit international trade, which is dominated by piperonal.

Seizures of all of the “ecstasy” precursors during the 2007-2012 period amounted to, on average, 13.5 tons or, expressed in 3,4-MDP-2-P equivalents (based on Board conversion ratios), 8.5 tons, equivalent to close to 1 per cent of global exports or imports of these substances.114 This is a higher rate than for potassium permanganate or acetic anhydride, although a lower rate than for amphetamine precursors.

A breakdown by subregion of seizures of “ecstasy” precursors during the 2007-2012 period shows that more than two thirds (69 per cent) of seizures were in East and South-East Asia and a fifth of them in North America, followed by Oceania (6 per cent) and Europe (4 per cent).

Safrole was seized primarily in East and South-East Asia (82 per cent of the total during the 2007-2012 period), is much larger in the Board data and more than offsets the smaller numbers reported by the Board in the other categories.

---

114 The calculation shows a ratio of 0.85 per cent for the 2007-2012 period. Based on trade statistics of the International Narcotics Control Board, the proportion amounted to 0.15 per cent during the 2007-2011 period (see Precursors Report, 2012, table 1).
followed by North America, Europe and the Oceania region. The largest seizures were reported by Thailand and Malaysia, followed by Australia, the United States, Canada and Cambodia. Average global seizures of safrole rose almost fourfold between the 1989-2006 period (3,042 litres per year) and the 2007-2012 period (11,381 litres).

Piperonal was seized mainly in North America (accounting for 95 per cent of the total during the 2007-2012 period), followed by Europe. Global piperonal seizures amounted to, on average, 1.1 tons per year during the 2007-2012 period, down from 2.9 tons per year during the 1989-2006 period.

The “traditional” precursor of “ecstasy”, 3,4-MDP-2-P, was seized mainly in North America (60 per cent during the 2007-2012 period) and in Oceania (35 per cent) and, to a lesser extent, in East and South-East Asia and Europe. The largest seizures were reported by Canada (60 per cent) and Australia (35 per cent). Global 3,4-MDP-2-P seizures amounted to, on average, 919 litres per year during the 2007-2012 period, down from 5,278 litres per year during the 1989-2006 period. China was often identified to be the most common source of this substance, although improved controls by that country have helped to reduce its availability. Given the shortage of illegal 3,4-MDP-2-P, there are indications, according to the Board, that India may be emerging as a new source.115

G. EFFECT OF PRECURSOR CONTROL ON THE SUPPLY OF ILLICIT DRUGS

The most obvious measure of the success of the precursor control system is the number of shipments that are stopped and the number of seizures made. There are, however, additional ways of measuring the effectiveness of precursor control, some of which are set out below.

1. Interception rates of diverted chemicals

Two figures are needed to estimate the interception rates of diverted chemicals: the amount seized and the amount required for the clandestine manufacture of the respective end product. The estimated amount of the chemicals required plus the amount seized gives an estimate of the total amount diverted. Expressing the seizures as a proportion of such diversions gives the interception rate.

Given the strong yearly fluctuations in seizures, the following calculations cover a longer period (2007-2012) and have been made for two substances: potassium permanganate and acetic anhydride. They reveal average interception rates of about 15 per cent of the chemicals diverted.

(a) Key chemical used in the manufacture of cocaine: potassium permanganate

Average annual global cocaine manufacture was an estimated 966 tons (range: 835-1,097 tons) over the period 2007-2012116. On average, some 385 tons of potassium permanganate (range: 167-603 tons) per year were required for such cocaine manufacture over this period. When seizures are included, this suggests that, on average, some 450 tons (range: 232-668 tons) of potassium permanganate were diverted from licit channels during the period 2007-2012, which gives a global interception rate of diverted potassium permanganate of about 15 per cent (range: 10-28 per cent) for the period 2007-2012117 (see table 3).

This is a rather high interception rate, given the small proportion of diverted potassium permanganate as compared with the global international trade in the substance (2 per cent of global exports of potassium permanganate were diverted during the period 2007-2012) (range: 1-3 per cent; see table 4).

Global cocaine manufacture declined by about a quarter over the period 2007-2012 (range: 23-30 per cent).118

| Table 3. Global interception rate of potassium permanganate for the period 2007-2012 |
|--------------------------------------|----------------|----------------|----------------|
| Average annual global cocaine manufacture, 2007-2012 (tons) | Minimum | Maximum | Midpoint |
| 835 | 1,097 | 966 |
| Amount of potassium permanganate needed for the manufacture of 100 kg of cocaine | 20 | 55 | - |
| Average annual amount of potassium permanganate required for illicit cocaine production (tons) | 167 | 603 | 385 |
| Average annual seizures of potassium permanganate (tons) | 65 | 65 | 65 |
| Average annual amounts diverted (tons) | 232 | 668 | 450 |
| Average annual interception rate (per cent)a | 10 | 28 | 15 |

Source: UNODC estimates based on World Drug Report data.

a Minimum: 65 tons/668 tons = 10 per cent; maximum: 65 tons/232 tons = 28 per cent.

118 World Drug Report data.
which suggests that diversions of potassium permanganate may have declined by similar proportions. Falling seizures of potassium permanganate over that period may also indicate a reduction in diversion attempts.

(b) Key chemical used in the manufacture of heroin: acetic anhydride

Global heroin manufacture was estimated at about 479 tons per year\(^{119}\) during the period 2007-2012, resulting in requirements for some 642,000 litres (range: 479,000-1,197,500 litres) of acetic anhydride per year for the manufacture of heroin.\(^{120}\) Including seizures,\(^{121}\) some 756,000 litres were diverted annually (range: 576,000-1,328,500) for use in the clandestine manufacture of heroin. That results in a global interception rate of about 15 per cent for acetic anhydride diverted for the manufacture of heroin\(^{122}\) (range: 7-22 per cent) (see table 5).

This can be considered a rather high interception rate, given the extremely small proportion of acetic anhydride that is actually diverted as compared with the global international trade in the substance (0.2 per cent of global imports of acetic anhydride during the period 2007-2012 (range: 0.14 per cent-0.33 per cent) (see table 6).

2. Reduction in drug availability

The present section focuses on the extent to which precursor control results in a reduction in the availability of drugs. A reduction in the availability of drugs may be brought about by seizing drugs or reducing the availability of the raw materials used in their manufacture. It must be pointed out, however, that the seizure of precursor chemicals is only one of the strategies used to reduce the illicit supply of precursors. The prime objectives of precursor control are preventing precursor chemicals from being diverted to

\(\footnotesize{119}\) The estimate of 479 tons has been calculated as the average of annual heroin manufacture estimates, which are derived from annual opium production (686 tons of heroin in 2007, 660 tons in 2008, 427 tons in 2009, 383 tons in 2010, 467 tons in 2011 and 311 tons in 2012). While the annual heroin figures derived from opium production estimates may be incorrect for individual years as a result of the accumulation or depletion of opium stocks in such years, over a longer period of time such changes in stocks, in general, do not play much of a role. This suggests that the 2007-2012 average may be a good estimate for actual average annual heroin manufacture during that period.

\(\footnotesize{120}\) According to International Narcotics Control Board data, between 1 and 2.5 litres of acetic anhydride are required for the manufacture of 1 kg of heroin (midpoint estimate of 1.75 litres). However, the bulk of the world’s heroin is manufactured in Afghanistan and, according to UNODC studies, the amounts of acetic anhydride used in Afghanistan typically range from 1 to 1.5 litres for a kilogram of heroin (midpoint 1.25 litres). Afghanistan accounted for 83 per cent of the world’s total opium production during the period 2007-2012. This gives a best estimate of about 1.34 litres of acetic anhydride per kilogram of heroin at the global level. The best estimate thus suggests that the heroin manufactured required some 642,000 litres of acetic anhydride. UNODC estimates are based on International Narcotics Control Board and World Drug Report data.

\(\footnotesize{121}\) Not all seizures of acetic anhydride have been related to the manufacture of heroin. Acetic anhydride is also used in the conversion of phenylacetic acid to P-2-P which is of particular importance in

\(\footnotesize{122}\) According to International Narcotics Control Board estimates, less than 17 per cent of globally diverted acetic anhydride was seized each year during the period 2007-2011 (International Narcotics Control Board, Precursors Report, 2012, para. 106).
illicit channels and identifying and dismantling clandestine laboratories. Thus, in quantitative terms, stopped shipments of suspicious chemicals are often more important than seizures of precursor chemicals. Nonetheless, seizures of precursor chemicals are quite significant when compared with seizures of end products.

(a) Seizures of precursor chemicals as compared with seizures of drugs

Another approach to assessing reductions in the availability of drugs is to compare seizures of precursor chemicals with seizures of drugs. This provides a comparison between the efforts, which target the end products, with precursor control efforts. Such an analysis for the period 2007-2012 reveals that seizures of potassium permanganate, expressed in terms of the amounts of cocaine that could have been produced with that chemical, were equivalent to about a third of actual cocaine seizures. The acetic anhydride seizures, expressed in terms of the amounts needed for heroin production, were almost equivalent to the total amounts of heroin and morphine seized. When converted into “ecstasy” equivalents, the total amount of “ecstasy” precursors seized over the period 2007-2012 exceeded actual “ecstasy” seizures by a fifth. When converted into amphetamine equivalents, total seizures of amphetamine and methamphetamine precursors were more than twice as high as actual seizures of amphetamine and methamphetamine (see table 7).

One of the explanations for the large amounts of amphetamine-type stimulant precursors seized could be that such precursors are often seized at the sites of clandestine laboratories. The amount of precursors often exceeds the end products found in those laboratories. An additional explanation is that the regions in which parts of the illegal production of amphetamine-type stimulants have traditionally taken place have invested heavily in precursor control in recent years. Moreover, much of the manufacture and consumption of amphetamines tends to be local or regional, while trade in or smuggling of precursor chemicals is often international and entails the crossing of borders. These aspects tend to facilitate the interception of precursors.

(b) Reductions in supply of drugs possibly linked to precursor control

Significant amounts of precursor chemicals have been intercepted in recent years. Taking precursors out of the market, however, may not be sufficient to yield a reduction in the supply of a drug. Nonetheless, in some cases, precursor control appears to have played a role in reducing the supply of drugs.

(i) Lysergic acid diethylamide

Lysergic acid diethylamide (LSD) was highly popular in several countries in the 1960s and the 1970s. However, consumption has declined in most parts of the world, including the main consumer markets, over the past two decades.

Data from England and Wales123 showed a decline in LSD use among 16-24 year olds from 4.5 per cent in 1996 to

</table>
0.4 per cent during the 2012-2013 period, a decline of 90 per cent. A number of surveys in other countries also showed strong declines in LSD use.\textsuperscript{124}

Data on secondary school students in the United States\textsuperscript{125} showed a decline of 75 per cent in the use of LSD during the period 1996-2013. That decline occurred alongside a strong decline in the reported availability of LSD in the country (reduction of 52 per cent during the period 1996-2013), which seems to have been the prevailing factor in explaining the decline in its use (see table 8).\textsuperscript{126} Improved controls over LSD precursors seem to have contributed to the reduction in the availability of LSD. Expressed in constant dollars, global exports of the main LSD precursors (ergotamine, ergometrine and lysergic acid) declined by 78 per cent between 1996 and 2012, which reduced the potential for diversion of those chemicals.\textsuperscript{127}

(ii) Methaqualone

There are indications that the misuse of methaqualone, a sedative-hypnotic drug that has similar effects to barbiturates, is less widespread than it used to be. Precursor control appears to have played a role in that reduction. Initially widely used in North America, often under the brand name Quaalude, and in Europe (notably in the United Kingdom) in the late 1960s and early 1970s, it was listed as a controlled substance in the 1971 Convention and was eventually withdrawn from many developed markets in the early 1980s. Though some clandestine laboratories in Mexico and other countries continued underground production in the 1980s, improved controls of N-acetylanthranilic acid and anthranilic acid appear to have haled those activities since the 1990s.

However, methaqualone use became increasingly concentrated in South Africa. In the 1980s and the early 1990s, methaqualone, known locally as Mandrax, was the second-most-used drug in the country (after cannabis). While it is still used in South Africa, there are indications that its usage has declined. In 2000, 33 per cent of all treatment related to psychoactive substances (excluding alcohol) in four South African towns was reported to have been related to Mandrax;\textsuperscript{128} this proportion fell to 19 per cent by 2011.\textsuperscript{129} The decline in methaqualone use around the world is also reflected in seizures: global seizures declined from a peak of 54 tons in 1994 to 11 tons in 2002 and 0.2 tons in 2012. India (47 per cent of total) and South Africa (45 per cent), followed by China (7 per cent), reported the largest seizures of methaqualone during the 2000-2012 period.\textsuperscript{130} At the same time, global legal exports of the two main methaqualone precursors, N-acetylanthranilic acid and anthranilic acid, fell by some 70 per cent between 2002 and 2012.\textsuperscript{131}

(iii) “Ecstasy”

The availability of MDMA ("ecstasy") has declined in recent years, which appears to have been largely a result of improved precursor control at the global level, notably in China.\textsuperscript{132}

Reduced availability had an impact on "ecstasy" use. Declines in the use of "ecstasy" were reported from a number of countries in Europe, North America and Oceania in recent years. In England and Wales, a key "ecstasy" market in Europe, use of the drug declined from a peak of 6.8 per cent among 16-24 year olds during the 2001-2002 period to 2.9 per cent during the 2012-2013 period.\textsuperscript{133}

\end{table}

\begin{itemize}
\item \textsuperscript{124} Annual prevalence of LSD use among young adults (aged 15-34) fell in Ireland from 2.9 per cent in 1998 to 0.6 per cent during the period 2010-2011; in Latvia from 1 per cent in 2003 to 0.1 per cent in 2011; and in Hungary from 1.3 per cent in 2001 to 0.3 per cent in 2007 (European Monitoring Centre for Drugs and Drug Addiction, Statistical Bulletin 2013 (Lisbon, 2013)).
\item \textsuperscript{125} See Lloyd D. Johnston and others, Monitoring the Future National Survey Results on Drug Use: 1975-2013 (Ann Arbor, University of Michigan, 2014).
\item \textsuperscript{126} The correlation between annual prevalence and perceived availability of LSD turned out to be very strong during the 1996-2013 period, amounting to $r = 0.93$ (statistically significant at $\alpha = 0.01$). The decline in perceived availability was much sharper than the decline in the perceived risk of harm during that period (see table 8).

\item \textsuperscript{133} Drug Misuse: Findings from the 2012 to 2013 Crime Survey for England and Wales.
\end{itemize}
This was not an exception: most European countries reported declines over the past few years and overall “ecstasy” consumption in countries of the European Union and the European Free Trade Association appears to have fallen by almost half among those aged 15-34 in recent years, based on a comparison of the pooled results of recent surveys for the 2007-2012 period with surveys for the 1998-2006 period. General population surveys also indicate declines in the use of “ecstasy” in Oceania, as well as a sharp decline (of more than 50 per cent) in North America in recent years (see figure 28).

Data from the ongoing United States study Monitoring the Future, undertaken by the Institute for Social Research at the University of Michigan, show that the annual prevalence rate of “ecstasy” use among students in the twelfth grade fell by 58 per cent between 2000 and 2013. That went hand in hand with a decline of about 32 per cent in the perceived availability of “ecstasy”. While the number of those who considered that there was a great risk in taking “ecstasy” increased between 2000 and 2005, they declined thereafter, and the perceived availability of “ecstasy” on the market declined during the 2000-2013 period (see table 9).

There are also indications in other countries that the decline in the availability of MDMA has played a key role in the decline of “ecstasy” use. Overall exports of “ecstasy” precursors fell by 41 per cent between 1998 and 2012. Average annual seizures of “ecstasy” precursors declined by

57 per cent during the 2007-2012 period compared with the 2000-2006 period. At the same time, average annual seizures of the end product, “ecstasy”, fell by 39 per cent over the same period and by 70 per cent between 2007 and 2012. The proportion of MDMA found in substances sold as “ecstasy” also declined.\textsuperscript{136} All those data suggest that improvements in the control of “ecstasy” precursors at the global level have played a key role in reducing the availability of MDMA, which, in turn, has been an important factor in the decline in “ecstasy” use.

\textbf{(c) Price: the case of acetic anhydride}

Another expected impact of precursor control should be a measurable increase in the prices paid by operators of clandestine laboratories, and hence in illicit production costs, as compared with the normal licit market prices. This is demonstrated in the case of acetic anhydride.

\textbf{(i) Import and export prices}

The average global export and import prices of acetic anhydride,\textsuperscript{137} if traded in large quantities, amount to about $1 per litre, according to UN COMTRADE data. They did not change much during the period 2007-2012. Export prices in all major exporting countries fluctuate around that figure. Similarly, according to a market analysis by the International Narcotics Control Board, wholesale prices for acetic anhydride fluctuate around $1.50 per litre.\textsuperscript{138}

Of 46 countries for which export prices could be established, 34 indicated an export price of less than $5 per litre over the 2007-2012 period. Higher export prices were reported by, inter alia, some countries along the Balkan route and countries along the “silk route”. Similarly, import prices exceeding $5 per litre were reported in, inter alia, several countries along the Balkan route and along the “silk route”, as well as countries in East and South-East Asia. It is not clear if the higher prices reflect different market dynamics or attempts by some intermediaries to purchase acetic anhydride for non-legal purposes.

\textbf{(ii) Prices paid by operators of clandestine heroin laboratories}

The prices paid by operators of clandestine laboratories, in general, tend to be far higher than those paid for acetic anhydride on the licit market. In Afghanistan, the world’s largest opium-producing and heroin-manufacturing country, average prices for acetic anhydride during the 2008-2011 period were reported to have ranged from $300 to $430 per litre (see figure 29), clearly exceeding the price of about $1 charged by the main licit suppliers of the substance.

\textbf{(iii) Differences in prices depending on the source}

Trafficking in acetic anhydride into Afghanistan emerged as a lucrative business as it had limited risks compared with drug trafficking even though traffickers are forced to take the more expensive option of smuggling acetic anhydride from countries where it has already been diverted. During the 2007-2010 period, the prices in Asia of acetic anhydride from illicit sources ranged from $4-$6 in the Republic of Korea, $12 in China and $60 in India to $200-$300 in Pakistan. In Europe, they were reported to have ranged from $25 in Slovakia and $100 in Bulgaria to $200-$225 in Turkey, all in 2010.\textsuperscript{139}

Nonetheless, some traders have been making extraordinarily high profits. In a seizures case in 2008, an Afghan trafficker admitted procuring 12 tons of acetic anhydride from the Republic of Korea, for which $50,000 had been paid.\textsuperscript{140} That equated to a purchase price of about $4 per litre, at a time when the average wholesale price of acetic anhydride in Nangarhar, Afghanistan, stood at about $300 per litre (see figure 29).

\textbf{(iv) Differences in price linked to perceived quality}

Prices also differ significantly according to perceived quality. In total, six different quality levels of acetic anhydride are regularly monitored in Afghanistan. The monthly price monitoring data for Afghanistan in 2013 showed a range from $76 per litre for quality “C” acetic anhydride in December 2013 to $247 per litre in July 2013 for quality

2. PRECURSOR CONTROL

“A” acetic anhydride. Differences in the price of acetic anhydride in Afghanistan often go hand in hand with differences in the perceptions of the origin of the substance.

(v) Changes of price over time

In addition, prices change significantly over time. Average annual prices of a litre of acetic anhydride amounted to an average of $24 (range: $13-$34) in Afghanistan in 1998. Following the ban on opium production in 2001, heroin manufacture also declined, as did the demand for acetic anhydride. As a consequence, acetic anhydride prices fell to a low of $8 per litre in Nangarhar in 2002. Average annual prices in Afghanistan as a whole increased thereafter to more than $430 per litre by 2011, before decreasing in 2012 and 2013.

Price increases over the 2002-2011 period, notably between 2007 and 2011, may be linked to improvements in precursor control. One element at the international level may have been the rescheduling of acetic anhydride from Table II to Table I of the 1988 Convention in 2001, which resulted in tightened international control, owing to the increasing use of pre-export notifications. In addition, various international cooperation efforts, such as Project Cohesion, reduced the readiness of companies to provide significant quantities of acetic anhydride to unknown or suspicious customers. In 2008, the Afghan authorities officially prohibited all imports of acetic anhydride. Precursor control efforts were also strengthened in Pakistan (which started seizing acetic anhydride 2008 onwards), the Islamic Republic of Iran and some other countries in the vicinity of Afghanistan. In parallel, average annual seizures of acetic anhydride at the global level rose from 46,000 litres per year during the 2004-2007 period to 147,000 litres per year during the 2008-2010 period, and then to 198,000 litres in 2011, thus contributing to a shortage on the Afghan market.

In 2012, however, global seizures of acetic anhydride fell by more than half to about 89,000 litres. At the same time, acetic anhydride prices in Afghanistan fell to $431 per litre to $230 per litre, which suggests that the availability may have increased.

Some of the increases in the price of acetic anhydride between 2002 and 2011 may also have been linked to the expansion of opium production in Afghanistan, and thus the higher demand for acetic anhydride to convert morphine into heroin. This relationship, however, is complex. Acetic anhydride prices in Afghanistan only partially followed the trends of opium production. In fact, the statistical correlation between Afghan opium production and acetic anhydride prices in Afghanistan during the 2002-2013 period is weak (r = 0.17), and not statistically significant.

In 2011, opium production, as well as seizures of heroin and morphine, increased sharply. The increase may have reflected an underlying growth in Afghan opiate manufacture, resulting in greater demand for acetic anhydride, which may explain the further price rise of that substance in 2011.

The situation changed again in 2012, when both opium production and heroin seizures fell in Afghanistan. The apparent decline in Afghan heroin manufacture seems to have prompted a decline in the demand for acetic anhydride. At the same time, the sharp decline in global seizures of acetic anhydride in 2012 may have eased the previous shortage of the chemical. In parallel, a worsening security situation facilitated the smuggling of acetic anhydride into the country. All of this contributed to a reduction of the risk premium and, thus, to lower acetic anhydride prices in 2012. The trend also continued in 2013, leading the International Narcotics Control Board to express fear that the supply of acetic anhydride may be rising again in Afghanistan.

(vi) Importance of the illicit acetic anhydride market in Afghanistan

Based on data contained in the UNODC study *The Opium Economy in Afghanistan: An International Problem*, the overall size of the acetic anhydride market may have been about $5 million in 2002. The market increased drastically over the next few years. By 2009, the total amount of acetic anhydride smuggled into Afghanistan was estimated at between 380 and 570 tons (midpoint estimate: 475 tons). Prices typically ranged between $250 and $450 per litre at the time, which resulted in a market value of between $130 and $200 million in 2009 (midpoint estimate: $165 million).

Based on data reported in UNODC, *Afghanistan: Opium Survey 2013*, demand for acetic anhydride may have amounted to between 525 and 735 tons in 2013 (midpoint estimate: 630 tons). As a result of falling prices, the overall acetic anhydride market in Afghanistan appears to have fallen to between $116 and $162 million (midpoint estimate: $140 million). That compares with a total (farm-gate) value of Afghan opium production of about $950 million in 2013, equivalent to about 0.7 per cent of Afghan GDP.

141 UNODC and Afghanistan, Ministry of Counter Narcotics, Afghanian drug price monitoring monthly reports.
148 UNODC and Ministry of Counter Narcotics of Afghanistan (December 2013).
149 In 2013, the UNODC annual opium survey estimated heroin manufacture in Afghanistan at between 350 and 490 tons, which would
(vii) Acetic anhydride as a cost factor in heroin manufacture

The high prices of acetic anhydride in Afghanistan during the 2008-2011 period, which ranged from $300-$430 per litre, became an important cost factor for Afghan heroin manufacturers.

An estimate of heroin manufacture costs in Afghanistan revealed that acetic anhydride accounted for a mere 2 per cent of the total in 2002.\textsuperscript{150} In contrast, an estimate in May 2010\textsuperscript{151} found overall production costs of about $1,600 per kilogram of brown heroin (up from less than $600 in 1998\textsuperscript{152}). The bulk of the cost came from opium (73 per cent) and acetic anhydride (26 per cent). Other chemicals such as activated carbon (charcoal), ammonium chloride, calcium oxide, hydrochloric acid, acetone and concentrated ammonia solutions accounted for just 1 per cent of the total cost.

The increase could have been even larger, but clandestine laboratory operators seem to have reacted to the rising prices of acetic anhydride by minimizing its use to about 1 litre per kilogram of heroin, often compromising on the quality of the heroin manufactured. While typical purity for Afghan heroin destined for overseas export had remained at about 70 per cent (range: 50-80 per cent)\textsuperscript{153} for years, data sent to UNODC by the Special Testing and Research Laboratory of the Drug Enforcement Administration of the United States showed that the average purity of heroin samples seized across Afghanistan had fallen to 37 per cent in 2007 and 32 per cent in 2008.\textsuperscript{154} The forensic laboratory of the Counter Narcotics Police of Afghanistan confirmed that many heroin samples continued to have a low level of purity in the first six months of 2011.\textsuperscript{155}

In 2011, the cost of acetic anhydride as a proportion of total heroin manufacture costs appeared to have remained at the same level as in 2010 (about 26 per cent), before declining in 2012 and 2013 as a result of falling acetic anhydride prices. Based on data reported in UNODC, Afghanistan: Opium Survey 2013, and based on the use of 1.5 litres of acetic anhydride per kilogram of heroin, the proportion of acetic anhydride in the overall production costs for heroin ($1,500-$1,600 per kilogram) declined to some 20 per cent of total manufacture costs by 2013. That is, however, still 10 times higher than in 2002 (see figure 30).

**H. REACTIONS OF CLANDESTINE OPERATORS FACING STRONGER PRECURSOR CONTROLS**

Improved precursor controls at the global level have prompted clandestine operators of illegal laboratories to develop a number of counterstrategies, including the use of more sophisticated ways to obtain precursor chemicals, and substitute them with non-controlled “pre-precursors” to manufacture the needed precursors, as well as the development of new psychoactive substances to which the current controls do not apply. While all of these counterstrategies constitute a challenge for the ongoing development of precursor control at the national, regional and international levels, they are at the same time an indication that precursor control is having an impact.

1. **More sophisticated ways to obtain precursor chemicals**

   (a) **Creation of specialized groups to obtain precursor chemicals**

   One of the strategies of operators of clandestine laboratories has been to hire specialists to organize the purchase of precursor chemicals. Such specialists are well aware of the actual status of the implementation of the 1988 Convention by various Governments. Moreover, they tend to be well connected and often can guarantee the supply of the chemicals. In general, chemical trafficking organizations have become increasingly resourceful, organized and adaptable in order to circumvent the growing number of control measures.\textsuperscript{156}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig30.png}
\caption{Estimated proportions of acetic anhydride in total heroin manufacture costs in Afghanistan, 2002-2013}
\end{figure}

\textsuperscript{150} UNODC, The Opium Economy in Afghanistan, p. 139.
\textsuperscript{151} UNODC, The Global Afghan Opium Trade, p. 151
\textsuperscript{152} UNODC, The Opium Economy in Afghanistan, p. 136.
\textsuperscript{154} In total, 41 heroin samples were analysed in 2008 and 40 samples in 2007. In 2007, the tested heroin samples had a purity ranging from less than 1 per cent to 86 per cent; in 2008 the purities ranged from less than 1 per cent to 91 per cent. Data suggested that the purity of heroin was low in the south of Afghanistan. In contrast, high purity levels were reported in Kabul in both 2007 and 2008 and heroin purity levels were also quite high in the north in 2007 and in the east in 2008.
\textsuperscript{156} International Narcotics Control Board, Precursors Report, 2011, para. 158.
2. PRECURSOR CONTROL

(b) Creation of front companies

Investigations made in El Salvador and Guatemala revealed the set-up of front companies or the use of existing companies operating in industries in which there is a well-established licit demand for the required chemicals. While the competent national authorities are, in general, well aware of the kind of business in which the controlled chemicals are used, it is far more difficult for them to identify actual requirements, as it is often possible to substitute one chemical for another. Unless regularly monitored, or if no inside information from competitors or employees is provided, such diversions of chemicals from licit front companies can remain undetected for many years. Nonetheless, the authorities in a number of countries have been successful in dismantling at least some such companies.157

(c) Identification of weak links in the international control system

Another strategy has been to identify weak links in the international control system and to use them as sources for the purchase of precursor chemicals. While practically all countries have signed and ratified the 1988 Convention (187 out of 193 United Nations Member States), there are still a number of countries that have not invoked article 12, paragraph 10 (a), of that Convention and do not require pre-export notifications.

This applies to a number of countries in Africa, as well as some countries in Central America, Western and Central Asia, South-East Asia and Oceania. Those countries are particularly vulnerable to being targeted as transit countries by precursor trafficking organizations.

The same applies to countries that have yet to register with the PEN Online system — mostly countries in Africa — and to countries that do not participate in PICS — again mostly African countries, as well as some countries in South America, the Near and Middle East, Central Asia, South-East Asia and Europe. In fact, the International Narcotics Control Board has in recent years identified a number of shipments of controlled chemicals that transited such countries in Africa, Central America, South America, the Near and Middle East, Central Asia, South-East Asia and the Balkan region.

A special case is Taiwan Province of China, which has a highly sophisticated chemical industry, including for the manufacture of several precursor chemicals; however, owing to its status, it does not participate in international precursor control efforts such as issuing pre-export notifications, participating in PICS and providing relevant information on seizures and suspicious shipments to the International Narcotics Control Board. According to the United States Department of State, in 2011 Taiwan Province of China was the third largest importer of ephedrine and the third largest exporter of pseudoephedrine worldwide.158 It also trades in a number of other substances under international control, including acetic anhydride. Methamphetamine laboratories have been detected by the authorities. Significant seizures of precursors in recent years have been made by the local authorities.159 Even though they may act in good faith, the mere fact that significant quantities of such substances are traded outside the international precursor control system constitutes an inherent risk that such trade flows may be diverted. The Board thus stressed in its latest report that “the current situation represents a significant weakness in the international control system.”160

(d) Identification of weaknesses at the national level (diversion from domestic sources)

Given the ongoing improvements in the control of the international trade in precursor chemicals, another strategy has been to identify weaknesses at the national level in individual countries. Organized criminal groups targeting precursor chemicals often do not wait until the chemicals enter the international market and thus become subject to tight monitoring. Instead, they divert the chemicals in the original manufacturing country, or in some subsequent transit country that has a legitimate demand for such chemicals. The chemicals are then smuggled out of that country to the final country of destination, thus bypassing the international control system developed for monitoring the international trade in such substances.

In this regard, the organizations trafficking precursor chemicals use methods similar to drug trafficking organizations. Their advantage, however, is that the customs and port authorities of most countries are not as well equipped to detect smuggled precursor chemicals as they are to detect smuggled drugs. Moreover, the penalties in most countries are less severe for trafficking of precursors than for drug trafficking, while profit margins can be very high.

(e) Use of the Internet

Another strategy has been to expand the supplier base by looking for new suppliers on the Internet. The specific problems related to the Internet addressed in chapter 1, in

157 In El Salvador and Guatemala, for instance, police investigated the operations of more than a dozen front companies, including companies involved in pesticides, clothes and furniture, that had been set up to smuggle precursor chemicals in large quantities from China into Central America in 2011 and 2012. The clandestine labs were apparently controlled by the Mexican Sinaloa cartel, and the final market for the methamphetamine was the United States. (Elyssa Pachico, “Investigations in El Salvador, Guatemala reveal thriving trade in precursor chemicals” (27 June 2012). Available from www.insightcrime.org.)

H. Reactions of clandestine operators facing stronger precursor controls

WORLD DRUG REPORT 2014

Over the years, the operators of clandestine laboratories have identified simple means for extracting pseudoephedrine from such preparations, e.g. by dissolving the tablets in isopropyl alcohol. (UNODC, Patterns and Trends of Amphetamine-Type Stimulants and other Drugs: Asia and the Pacific, 2011, p. 43.)

2. Use of alternative precursors

(a) Pharmaceutical preparations

One way to circumvent the rules governing the international trade in bulk chemicals has been to focus on pharmaceutical preparations containing precursor chemicals. Pharmaceutical preparations are largely excluded by the 1988 Convention, which states, in article 12, paragraph 14, “The provisions of this article shall not apply to pharmaceutical preparations, nor to other preparations containing substances in Table I or Table II that are compounded in such a way that such substances cannot be easily used or recovered by readily applicable means”. The lack of controls has, in particular, affected pharmaceutical preparations containing ephedrine and pseudoephedrine. While such substances contained in nasal decongestants, bronchodilators and various cold medicines have positive properties for persons in need, they can be misused.

In this context, in the 2009 Political Declaration and Plan of Action, Member States were explicitly asked to prevent the diversion of such pharmaceutical preparations from domestic and international trade (Plan of Action, para. 41 (s)). In the light of continuing challenges, the Commission on Narcotic Drugs adopted resolution 54/8 in March 2011, in which Governments were encouraged to adopt regulatory frameworks to control the production, distribution and commercialization of pharmaceutical preparations containing ephedrine and pseudoephedrine, to utilize the PEN Online system and to apply similar control measures for such pharmaceutical preparations as for bulk precursor chemicals.

Global seizures of pharmaceutical preparations containing ephedrine or pseudoephedrine increased from negligible levels in the 1990s to 5.6 tons in 2006 and 36.1 tons in 2011 before falling again to 4.1 tons in 2012. The largest diversions of ephedrine and pseudoephedrine preparations over the period 2007-2012 were reported from North America (60 per cent) and East and South-East Asia (20 per cent), the two largest methamphetamine-producing regions, followed by the Oceanian region (10 per cent), Europe (4 per cent), South Asia (4 per cent), and Central America and the Caribbean (2 per cent); smaller amounts were seized in South America and West Asia. The number of Governments reporting seizures of pharmaceutical preparations containing such substances amounted to 37 over the period 2007-2012, including 18 reporting seizures of ephedrine preparations and 28 reporting seizures of pseudoephedrine preparations. About 17 per cent of all ephedrine and pseudoephedrine seizures over that period were in the form of pharmaceutical preparations.

Awareness of such problems rose following a number of operations conducted under the auspices of Project Prism in recent years. While in Operation Crystal Flow, conducted in 2007, more than 90 per cent of the ephedrine and pseudoephedrine seizures were still related to bulk ephedrine and pseudoephedrine, that proportion fell to less than 75 per cent in Operation Ice Block in 2008 and to just a third in Operation Pila, conducted in 2009 and early 2010.

Post-operational communications issued between April 2010 and August 2012 led to the seizure of 8.8 tons of ephedrine in bulk and more than 24 tons in the form of preparations, i.e. 73 per cent of the ephedrine and pseudoephedrine seized was in the form of pharmaceutical preparations, clearly indicating the rapidly growing role of pharmaceutical preparations as inputs for the manufacture of methamphetamine. Before 2010, several of the stopped shipments of pseudoephedrine preparations went from South Asia and South-East Asia with the destination of Central America and Mexico, but the shipments to Mexico have declined following stricter controls in that country.

(b) Use of substitute chemicals and “pre-precursors”

Another strategy of the operators of clandestine laboratories has been to shift from substances controlled under the 1988 Convention to non-controlled substitute chemicals and/or to non-controlled “pre-precursors”. Instructions on the use of such chemicals are also available on the internet.

Examples of such substitute chemicals for the manufacture of amphetamine or methamphetamine are: APAAN, various esters of phenylacetate and P-2-P bisulfite adduct (see figure 31). An example for the manufacture of “ecstasy” is 3,4-MDP-2-P methyl glycidate, sometimes abbreviated as MMDMG or PMK-glycidate. Substances such as the bisulfite adduct of P-2-P and MMDMG are often also referred to as “masked” precursors, as their use helps criminals to conceal the normal form of precursors of amphetamine-type stimulants by packaging and smuggling them in a way that has heretofore been rather uncommon and thus difficult for law enforcement agencies to detect.

161 Over the years, the operators of clandestine laboratories have identified simple means for extracting pseudoephedrine from such preparations, e.g. by dissolving the tablets in isopropyl alcohol. (UNODC, Patterns and Trends of Amphetamine-Type Stimulants and other Drugs: Asia and the Pacific, 2011, p. 43.)

2. PRECURSOR CONTROL

(i) alpha-Phenylacetoacetonitrile: a precursor for P-2-P

An example of the use of substitute chemicals has been the ever wider use of APAAN, until recently a non-controlled precursor that can be easily converted into P-2-P at a ratio of 1.4 to 1.167 It emerged as a substitute chemical for P-2-P-based manufacture of methamphetamine in Asia and for P-2-P-based amphetamine laboratories in Europe, thus circumventing the improved controls over P-2-P.

APAAN was originally discovered in a large-scale methamphetamine manufacturing laboratory in Malaysia in 2006, and since 2009 has been seized in various European countries.168 The International Narcotics Control Board reported that in 2011 three European countries seized APAAN totalling more than 3.5 tons, of which the bulk was seized in the Netherlands.169 For 2012, six European countries reported seizures totalling 17.5 tons, with the largest seizures reported from Belgium, the Netherlands and Hungary. Seizures of P-2-P, in contrast, declined in Europe from some 5,500 litres in 2010 to 2,700 litres in 2011 and 800 litres in 2012,170 possibly indicating a shift away from P-2-P towards APAAN.

Between April and October 2012, authorities in Belgium, Bulgaria, the Netherlands and Romania communicated 17 incidents involving 13.6 tons of APAAN, all of which originated in China. Over the period November 2012-October 2013, 29 incidents were communicated, affecting Austria, Belgium, Estonia, France, Germany, Latvia, Luxembourg and the Netherlands, with the latter country accounting for almost half of all incidents.171 It appears that the final destination of the shipments was the Netherlands, while the shipments of APAAN typically originated in China.172

The misuse of APAAN, however, is not just a European problem. In 2012, Canada informed other countries of the seizure of two shipments of APAAN totalling 6.7 tons. The two shipments originated in China.173

The increased trafficking in APAAN has been attributed to its availability and low cost. As a consequence, the International Narcotics Control Board recommended to the Commission on Narcotic Drugs that APAAN be included in Table I of the 1988 Convention.174

(ii) Esters of phenylacetic acid and other non-scheduled precursors for the manufacture of amphetamines

Ethyl phenylacetate and methyl phenylacetate

Another example of the spread of non-controlled substances as precursor chemicals has been the use of various

167 International Narcotics Control Board, Precursors Report, 2013, para. 82.
171 Ibid., para. 85.
172 Ibid., para. 84.
174 The Board sent an official communication to the UN Secretary-General to formally initiate procedures for the scheduling of APAAN in March 2013. The Secretary-General invited Member States to express their opinion. A total of 42 Governments responded to the questionnaire, which confirmed that there was practically no legitimate use of that substance for industry. On the basis of those responses, the Board submitted a recommendation to the Commission on Narcotic Drugs to include APAAN in Table I of the 1988 Convention, and the Commission approved that proposal in March 2014.
esters of phenylacetic acid.\textsuperscript{175} While phenylacetic acid is a controlled substance under the 1988 Convention, this is not the case for its esters.\textsuperscript{176} Examples of such trafficked esters are ethyl phenylacetate and methyl phenylacetate. Both can be easily converted into phenylacetic acid.

Significant amounts of such esters were seized as part of the International Narcotics Control Board’s Operation Phenylacetic Acid and its Derivatives, launched in March 2011. It led to seizures of some 610 tons of derivatives of phenylacetic acid in ports, warehouses and laboratories in Latin America. Mexico alone seized 421 tons. The operation also led to important seizures in Belize, El Salvador, Guatemala and Nicaragua. Ethyl phenylacetate was the most commonly identified ester.\textsuperscript{177} Mexico seized 369 tons and 177,000 litres of ethyl phenylacetate in 2011 and El Salvador seized 157 tons. In addition, Mexico seized 313,000 litres of methyl phenylacetate in 2011. Those were substantial amounts, exceeding seizures of other methamphetamine precursors.\textsuperscript{178}

Though there have been declines in seizures since 2011, they remain significant. Authorities in Mexico, where ethyl phenylacetate has been under control since 2009, reported the seizure of 72 tons and 46,000 litres in 2012.\textsuperscript{179} and Guatemala reported the seizure of 16 tons in a warehouse in 2012. As in previous incidents, the chemical had originated in China.\textsuperscript{180}

Despite extensive misuse of the esters of phenylacetic acid for the clandestine manufacture of methamphetamine, no attempts have been made to schedule them at the international level.

(iii) Phenylacetamide, benzylchloride, hypophosphorous acid, styrene, benzaldehyde and benzyl cyanide

Even if all of the esters of phenylacetic acid were controlled, there would still be a large number of substitute chemicals available. For instance, the Mexican authorities reported the seizure in 2011 of a variety of other non-scheduled chemicals used in the manufacture of methamphetamine, including phenylacetamide (300 tons), benzylchloride (77,000 litres) and small amounts of 2-phenylethanol. Earlier, the Mexican authorities had reported seizures of hypophosphorous acid (1,941 litres in 2009). Large amounts of that substance were also seized in Canada (9.8 tons). In 2012, the Australian authorities reported the seizure of 11 tons of hypophosphorous acid in New South Wales.\textsuperscript{181}

In June 2012, the Mexican authorities dismantled a methamphetamine laboratory where styrene, an industrial starting material for the production of plastics (polystyrene), was used as a key precursor. In 2007, there was a report of some smaller seizures of styrene in Australia.\textsuperscript{182}

In Europe and in Asia, Governments have reported seizures of a number of other non-scheduled pre-precursors for P-2-P in recent years, including benzaldehyde and benzyl cyanide. Larger amounts were seized in the Philippines (2,400 litres), while smaller amounts of benzaldehyde (less than 100 kg) were seized in 2012 in Estonia, Germany, Hungary, Poland and the Russian Federation. In 2012, attempts were also made to smuggle benzyl cyanide to Lebanon (520 litres), together with equipment for illicit amphetamine manufacture.\textsuperscript{183}

(iv) Substitute chemicals for the manufacture of “ecstasy”: 3,4-MDP-2-P methyl glycidate

Substitute chemicals have also emerged for the manufacture of MDMA (“ecstasy”), notably following the introduction of improved controls over 3,4-MDP-2-P by China. This led to a shortage of “ecstasy” precursors over the period 2007-2010. In the Netherlands, which is identified by many European countries as the source of “ecstasy”, the content of MDMA in products sold as “ecstasy” fell from some 90 per cent over the 2000-2004 period to around 70 per cent in 2009 before recovering to 82 per cent in 2010 and 91 per cent in 2011.\textsuperscript{184} Recent trends indicate a further recovery of the “ecstasy” market. This has been made possible by the increasing use of safer “ecstasy” and the “discovery” of a number of non-controlled substitute chemicals. One such chemical is 3,4-MDP-2-P methyl glycidate, which can be easily converted into 3,4-MDP-2-P. It is frequently made out of piperonal (a controlled “ecstasy” precursor).\textsuperscript{185} 3,4-MDP-2-P methyl glycidate was initially detected in Australia in 2004, following the seizure of a 44-gallon drum mislabelled as glycidyl methacrylate, which the authorities expected to be linked to MDMA production.\textsuperscript{186} In 2010

\textsuperscript{175} UNODC, Global Smart Update 2012, vol. 7, March 2012, pp. 5-6.

\textsuperscript{181} International Narcotics Control Board, Precursors Report, 2013, para. 93.

\textsuperscript{183} International Narcotics Control Board, Precursors Report, 2013, para. 92.

\textsuperscript{184} European Monitoring Centre for Drugs and Drug Addiction – Trimbo instituut, Report by the Reitox National Focal Point The Netherlands Drug Situation 2012, p. 154 (and previous years).

\textsuperscript{185} UNODC, Global Smart Update, vol. 7, March 2012, pp. 4-5.

the substance was found in the Netherlands, together with instructions on how to convert it into "ecstasy". In total, the Netherlands authorities seized 1.2 tons of the substance in 2010, including 1 ton seized in an air-freight shipment from China that had been mislabelled. Subsequently, the substance also appeared in Slovakia, Belgium, Poland and Estonia as well as in Denmark in a shipment that had originated in China and was destined for the Netherlands. Over the period November 2012–November 2013, the Netherlands authorities reported the seizure of only 690 grams of 3,4-MDP-2-P methyl glycidate, intercepted at the Amsterdam airport in a package sent from China via a courier service to the Netherlands. The substance was mislabelled as methyl cellulose.

(v) Methylamine: a universal precursor in the manufacture of amphetamine-type stimulants

Methylamine is another non-scheduled chemical that has emerged in recent years in the clandestine manufacture of amphetamine-type stimulants. When combined with P-2-P, it can be used for the manufacture of methamphetamine or, if combined with 3,4-MDP-2-P, it can produce "ecstasy".

On the basis of seizure patterns, the largest amounts of this chemical appear to be currently used for the manufacture of methamphetamine. Seizures of methylamine have been reported in increasing numbers since 2004, primarily by countries in North America, though seizures have also been made in Oceania, Europe and East and South-East Asia.

Following years of seizures totalling a few hundred kilograms, the amounts seized rose to 665 tons and 478,000 litres in 2011 (see figure 32). Large-scale seizures also continued in 2012 (197 tons and 208,000 litres). Though smaller than a year earlier, they still exceeded seizures of "traditional" precursors of amphetamine-type stimulants (less than 50 tons in 2012).

The largest seizures of methylamine in recent years have been reported by Mexico, where this chemical has been controlled since November 2009. In 2010, Mexico reported seizures of 44.3 tons and 47,300 litres of methylamine and it accounted for more than 90 per cent of global seizures of this substance. The next largest seizures were reported by the Netherlands, followed by Canada and the United States. By mid-2011, Mexico had reported three seizures of methylamine at seaports, totalling more than 154,000 litres, originating in China. Large seizures were also reported in some countries in Central America. El Salvador seized almost 69 tons in two shipments in June 2011, destined for Guatemala. In 2011, Mexico accounted for 56 per cent of global seizures of methylamine, followed by the United States (38 per cent). In 2012, seizures of methylamine took place again primarily in Mexico (197 tons and 150,000 litres), followed by Honduras (51,000 litres), the United States (6,929 litres) and Poland (403 litres).

3. Production of new psychoactive substances

Another strategy to circumvent controls of precursor chemicals has been to opt for the manufacture of new psychoactive substances. As of end-2013, 348 such substances had been identified, exceeding the number of substances already under international control (234 in 2013). The categories of such substances most frequently identified have been, in order of frequency, synthetic

191 Ibid., para. 90.
192 Global seizures in 2012: pseudoephedrine, 25 tons; ephedrine, 7 tons; P-2-P, 6,800 litres; phenylacetic acid, 2 tons; safrole, 2,000 litres; piperonal, 336 kg; 3,4-MDP-2-P, 228 litres; isosafrole, 10 litres (International Narcotics Control Board, Precursors Report, 2013, p. 81).
cannabinoids, phenethylamines, synthetic cathinones, tryptamines, various plant-based substances, piperazines, phencyclidines and ketamine, as well as aminooindanes. Given the lack of a global control mechanism for new psychoactive substances, the chemicals needed to produce them are, in general, easy to obtain. This offers plenty of opportunities for operators of clandestine laboratories to acquire such chemicals and use them in the manufacture of new psychoactive substances. Nonetheless, for the time being, trafficking in these chemicals at the global level seems to be rather limited.

I. CONCLUDING REMARKS

The analysis of the precursor control sector highlights the substantial progress made over the past two decades, since the international community, in the 1988 Convention, adopted precursor control as one of its strategies to fight illegal drug production. While drug production has not been eliminated by the introduction of precursor control measures, there is sufficient evidence to show that precursor control has had an impact on the illicit manufacture of some drugs. Over the period 2007-2012, about 15 per cent of the diverted precursor chemicals acetic anhydride and potassium permanganate was seized. Reductions in LSD use and “ecstasy” use in recent years appear to have been linked, inter alia, to improved precursor controls.

The new strategies of operators of clandestine laboratories clearly highlight, at the same time, the challenges that precursor control will face in the future, as ever more new chemical substances emerge and are able to replace “traditional” precursor chemicals.

Some of the instruments for dealing with this problem are already in place. In line with the request contained in the Political Declaration adopted by the General Assembly at its twentieth special session, in 1998, and its related action plan on precursor chemicals, a limited international special surveillance list of substances not in Tables I and II of the 1988 Convention is regularly prepared and updated by the International Narcotics Control Board to help authorities to identify potential precursor shipments. The 1998 action plan on precursors also provided that Member States should apply monitoring measures, in cooperation with the chemical industry, to prevent the diversion of substances included on the special surveillance list, and Member States were asked to consider making the diversion of non-scheduled chemical substances a criminal offence. Moreover, in the 2009 Political Declaration and Plan of Action, Member States were invited to expand the use of pre-export notifications to include non-scheduled substances and pharmaceutical preparations. In the 2009 Plan of Action, Member States were also asked to increase efforts to prevent precursors from domestic channels from being smuggled across borders.

While all of these actions have been agreed on by Member States, they await implementation in a number of countries. The challenge is the effective and universal implementation of the international instruments.

At the same time, it is important to note that most precursor chemicals have a wide spectrum of legitimate uses. Any control system, whether local or international, must thus be aimed at effectively limiting the availability of such chemicals for operators of clandestine laboratories, while guaranteeing that licit manufacture of, trade in and use of such chemicals are not jeopardized.

Sources: For Bolivia (Plurinational State of), 2002: CICAD and United States Department of State, International Narcotics Control Strategy Report; since 2003: national illicit crop monitoring system supported by UNODC. For Colombia and Peru: national illicit crop monitoring system supported by UNODC.

Note: An account of the different concepts for different areas and their effect on comparability was presented in the World Drug Report 2012 (pp. 41-42). In the continuing efforts to improve comparability of estimates between countries, the estimated net area under coca bush cultivation at the reference date of 31 December is presented for Peru in addition to the area under coca bush cultivation in Peru as seen on satellite imagery. The reference date of 31 December is also used for the estimated area under coca bush cultivation in Colombia. The estimates presented for the Plurinational State of Bolivia represent the area under coca bush cultivation as seen on satellite imagery.

- a Net area on 31 December. Estimates from 2009 were adjusted for small fields, while estimates for previous years did not require that adjustment.
- b Net area on 31 December.
- c Area as interpreted from satellite imagery.
- d The global coca cultivation figure was calculated using the area as interpreted on satellite imagery for Peru.

Sources: National Illicit Crop Monitoring System supported by UNODC.
Notes: Owing to the introduction of an adjustment factor for small fields, estimates since 2010 are not directly comparable with those of previous years. The ranges reflect the uncertainty associated with the estimates. For Bolivia (Plurinational State of) and Peru, the ranges are based on confidence intervals, and the best estimate is the midpoint between the upper and lower bounds of the range. In the case of Colombia, the range is estimated on the basis of the area under coca cultivation in the two previous years. The methodology used to calculate uncertainty ranges for production estimates is still under development, and figures may be revised when more information becomes available.

Sources: For Bolivia (Plurinational State of): Government calculations based on coca leaf yield surveys by UNODC (Yungas of La Paz) and United States DEA scientific studies (Chapare). For Colombia: national illicit crop monitoring system supported by UNODC and DEA scientific studies. Due to the introduction of an adjustment factor for small fields, estimates since 2010 are not directly comparable with those of previous years. For Peru: Government calculations, based on a coca leaf to cocaine conversion ratio from DEA scientific studies.
Notes: Owing to the ongoing review of conversion factors, no point estimate of the level of cocaine production could be provided since 2009. Because of uncertainty about the level of total potential cocaine manufacture and about the comparability of the estimates of the various countries, the figures were estimated as ranges (842-1,111 tons in 2009, 788-1,060 tons in 2010, 776-1,051 tons in 2011 and 714-973 tons in 2012). Detailed information on the ongoing revision of conversion ratios and cocaine laboratory efficiency is available in the World Drug Report 2010 (p. 249). Figures in italics are being reviewed. Information on estimation methodologies and definitions can be found in the section on methodology in the online version of this report.

Sources: UNODC annual report questionnaire and database on estimates and long-term trend analysis (DELTA); Government of Bolivia (Plurinational State of), Colombia and Peru.
Notes: Totals for Bolivia (Plurinational State of) since 2006 include voluntary and forced eradication. Totals for Peru include voluntary and forced eradication. Two dots (..) indicate that data are not available.

Notes: Seizure data are based on aggregates of seized cocaine salts, “crack” cocaine, cocaine base, coca paste and unspecified cocaine. Due to the paucity of data, price data and seizure data are not adjusted for purity. In order to preserve comparability between countries and over time, price data are based on records of cocaine salts only. All averages are weighted by population. Two dots (..) indicate insufficient data.

aAn international dollar would buy in the region concerned a comparable amount of goods and services a United States Dollar would buy in the United States.

Note: Figures in italics are preliminary and may be revised when updated information becomes available. Information on estimation methodologies and definitions can be found in the methodology section of the online version of the present report.

a May include areas that were eradicated after the date of the area survey.
b Owing to continuing low cultivation, figures for Viet Nam (as of 2000) and Thailand (as of 2003) were included in the category “Other countries”.
c The Government of Mexico does not validate the estimates provided by the United States, as they are not part of its official figures and it does not have information on the methodology used to calculate them. The Government of Mexico is in the process of implementing a monitoring system in collaboration with UNODC to estimate illicit cultivation and production.
d Eradication and plant seizure reports from different sources indicate that illicit opium poppy cultivation also exists in the following subregions: North Africa, Central Asia and Transcaucasia, Near and Middle East/South-West Asia, South Asia, East and South-East Asia, Eastern Europe, South-Eastern Europe, Central America and South America. Starting in 2008, a new methodology was introduced to estimate opium poppy cultivation and opium/heroin production in those countries. The estimates are higher than the previous figures but have a similar order of magnitude. A detailed description of the estimation methodology is available in the online version of the present report.

Note: Figures in italics are preliminary and may be revised when updated information becomes available. Information on estimation methodologies and definitions can be found in the methodology section of the online version of the present report. The opium production estimates for Afghanistan for 2006-2009 were revised after data quality checks revealed an overestimation of opium yield estimates in those years.

a Owing to continuing low cultivation, figures for Viet Nam (as of 2000) and Thailand (as of 2003) were included in the category “Other countries”.

b The Government of Mexico does not validate the estimates provided by the United States, as they are not part of its official figures and it does not have information on the methodology used to calculate them. The Government of Mexico is in the process of implementing a monitoring system in collaboration with UNODC to estimate illicit cultivation and production.

c Eradication and plant seizure reports from different sources indicate that illicit opium poppy cultivation also exists in the following subregions: North Africa, Central Asia and Transcaucasia, Near and Middle East/South-West Asia, South Asia, East and South-East Asia, Eastern Europe, South-Eastern Europe, Central America and South America. Starting in 2008, a new methodology was introduced to estimate opium poppy cultivation and opium/heroin production in those countries. The estimates are higher than the previous figures but have a similar order of magnitude. A detailed description of the estimation methodology is available in the online version of the present report.

<td>560</td>
</tr>
</tbody>
</table>

Notes: Only for Afghanistan, the proportion of potential opium production which is not converted into heroin within the country could be estimated. For all other countries, for the purpose of this table, it is assumed that all opium potentially produced is converted into heroin. If the total potential opium production in Afghanistan in 2012 were converted into heroin, the total potential heroin production in Afghanistan would be 786 tons and global production would be total 923 tons. The estimates for 2006 - 2009 were revised due to the revision of opium production figures for Afghanistan. Figures in italics are preliminary and may be revised when updated information becomes available.

Sources: UNODC annual reports questionnaire, Government reports, reports of regional bodies, and the United States International Narcotics Control Strategy Report

Notes: In this table, only eradication reported in terms of area is considered. Eradication reported in terms of number of plant seizures can be found in the annex on seizures of the electronic version of the World Drug Report located at https://www.unodc.org/wdr/  

a Although eradication took place in 2004, it was not officially reported to UNODC.

Regional groupings

This report uses a number of regional and subregional designations. These are not official designations. They are defined as follows:

- **East Africa**: Burundi, Comoros, Djibouti, Eritrea, Ethiopia, Kenya, Madagascar, Mauritius, Rwanda, Seychelles, Somalia, Uganda and United Republic of Tanzania.
- **North Africa**: Algeria, Egypt, Libya, Morocco, South Sudan, Sudan and Tunisia.
- **Southern Africa**: Angola, Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Swaziland, Zambia and Zimbabwe.
- **West and Central Africa**: Benin, Burkina Faso, Cameroon, Cabo Verde, Central African Republic, Chad, Congo, Côte d’Ivoire, Democratic Republic of the Congo, Equatorial Guinea, Gabon, Gambia, Ghana, Guinea, Guinea-Bissau, Liberia, Mali, Mauritania, Niger, Nigeria, Sao Tome and Principe, Senegal, Sierra Leone and Togo.
- **Caribbean**: Antigua and Barbuda, Bahamas, Barbados, Bermuda, Cuba, Dominica, Dominican Republic, Grenada, Haiti, Jamaica, Saint Kitts and Nevis, Saint Lucia, Saint Vincent and the Grenadines and Trinidad and Tobago.
- **Central America**: Belize, Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua and Panama.
- **North America**: Canada, Mexico and United States of America.
- **South America**: Argentina, Bolivia (Plurinational State of), Brazil, Chile, Colombia, Ecuador, Guyana, Paraguay, Peru, Suriname, Uruguay and Venezuela (Bolivian Republic of).
- **Central Asia and Transcaucasia**: Armenia, Azerbaijan, Georgia, Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan and Uzbekistan.
- **East and South-East Asia**: Brunei Darussalam, Cambodia, China, Democratic People’s Republic of Korea, Indonesia, Japan, Lao People’s Democratic Republic, Malaysia, Mongolia, Myanmar, Philippines, Republic of Korea, Singapore, Thailand, Timor-Leste and Viet Nam.
- **Near and Middle East/South-West Asia**: Afghanistan, Bahrain, Iran (Islamic Republic of), Iraq, Israel, Jordan, Kuwait, Lebanon, Oman, Pakistan, Qatar, Saudi Arabia, Syrian Arab Republic, United Arab Emirates and Yemen. The Near and Middle East refers to a sub-region that includes Bahrain, Israel, Jordan, Kuwait, Lebanon, Oman, Qatar, Saudi Arabia, the Syrian Arab Republic, the United Arab Emirates and Yemen.
- **South Asia**: Bangladesh, Bhutan, India, Maldives, Nepal and Sri Lanka.
- **Eastern Europe**: Belarus, Republic of Moldova, Russian Federation and Ukraine.
- **South-Eastern Europe**: Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Montenegro, Romania, Serbia, the former Yugoslav Republic of Macedonia and Turkey.
- **Western and Central Europe**: Andorra, Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Liechtenstein, Lithuania, Luxembourg, Malta, Monaco, Netherlands, Norway, Poland, Portugal, San Marino, Slovakia, Slovenia, Spain, Sweden, Switzerland and United Kingdom of Great Britain and Northern Ireland.
- **Oceania**: Australia, Fiji, Kiribati, Marshall Islands, Micronesia (Federated States of), Nauru, New Zealand, Palau, Papua New Guinea, Samoa, Solomon Islands, Tonga, Tuvalu, Vanuatu and small island territories.
ampheta-mine-type stimulants — a group of substances composed of synthetic stimulants that were placed under international control in the Convention on Psychotropic Substances of 1971 and are from the group of substances called amphetamines, which includes amphetamine, methamphetamine, methcathinone and the “ecstasy”-group substances (3,4-methylenedioxymethamphetamine (MDMA) and its analogues)

annual prevalence — the total number of people of a given age range who have used a given drug at least once in the past year divided by the number of people of the given age range

coca paste (or coca base) — an extract of the leaves of the coca bush. Purification of coca paste yields cocaine (base and hydrochloride)

crack cocaine — cocaine base obtained from cocaine hydrochloride through conversion processes to make it suitable for smoking

new psychoactive substances — substances of abuse, either in a pure form or a preparation, that are not controlled under the Single Convention on Narcotic Drugs of 1961 or the 1971 Convention, but which may pose a public health threat. In this context, the term “new” does not necessarily refer to new inventions but to substances that have become available in recent years

opioids — a generic term applied to alkaloids from opium poppy, their synthetic analogues and compounds synthesized in the body

opiates — a subset of opioids comprising the various products derived from the opium poppy plant, including opium, morphine and heroin

poppy straw — all parts (except the seeds) of the opium poppy, after mowing

problem drug users — people who engage in the high-risk consumption of drugs, for example people who inject drugs, people who use drugs on a daily basis and/or people diagnosed with drug use disorders or as drug-dependent based on clinical criteria contained in the International Classification of Diseases (tenth revision) of the World Health Organization and the Diagnostic and Statistical Manual of Mental Disorders (fourth edition) of the American Psychiatric Association, or any similar criteria or definition that may be used
